Apache ShardingSphere document

Apache ShardingSphere

Jan 09, 2024
1 What is ShardingSphere

1.1 Introduction ............................................. 1
  1.1.1 ShardingSphere-JDBC ................................ 1
  1.1.2 ShardingSphere-Proxy .............................. 1
1.2 Product Features ........................................... 2
1.3 Advantages .................................................. 2

2 Design Philosophy

2.1 Connect: Create database upper level standard ............... 5
2.2 Enhance: Database computing enhancement engine .......... 5
2.3 Pluggable: Building database function ecology ............. 5
  2.3.1 L1 Kernel Layer .......................................... 6
  2.3.2 L2 Feature Layer .......................................... 6
  2.3.3 L3 Ecosystem Layer ....................................... 6

3 Deployment

3.1 Using ShardingSphere-JDBC ................................. 7
3.2 Using ShardingSphere-Proxy ................................. 8
3.3 Hybrid Architecture .......................................... 9

4 Running Modes

4.1 Standalone Mode ........................................... 11
4.2 Cluster Mode ............................................... 11

5 Roadmap ......................................................... 12

6 Get Involved ..................................................... 13

7 Quick Start

7.1 ShardingSphere-JDBC ........................................ 14
  7.1.1 Scenarios .................................................. 14
  7.1.2 Limitations ............................................... 14
  7.1.3 Requirements ............................................. 14
## 7.1 Procedure

14

### 7.2 ShardingSphere-Proxy

16

#### 7.2.1 Scenarios

16

#### 7.2.2 Limitations

16

#### 7.2.3 Requirements

17

#### 7.2.4 Procedure

17

## 8 Features

19

### 8.1 Sharding

19

#### 8.1.1 Background

19

- Vertical Sharding

20

- Horizontal Sharding

21

#### 8.1.2 Challenges

22

#### 8.1.3 Goal

22

#### 8.1.4 Application Scenarios

22

- Mass data high concurrency in OLTP scenarios

22

- Mass data real-time analysis in OLAP scenarios

23

#### 8.1.5 Related References

23

#### 8.1.6 Core Concept

23

- Table

23

- Data Nodes

25

- Sharding

26

#### 8.1.7 Limitations

29

- Stable Support

29

- Experimental Support

31

- Do not Support

32

#### 8.1.8 Appendix with SQL operator

32

### 8.2 Distributed Transaction

33

#### 8.2.1 Background

33

#### 8.2.2 Challenge

33

#### 8.2.3 Goal

34

#### 8.2.4 How it works

34

- LOCAL Transaction

34

- XA Transaction

34

- BASE Transaction

35

#### 8.2.5 Application Scenarios

36

- Application Scenarios for ShardingSphere XA Transactions

36

- Application Scenarios for ShardingSphere BASE Transaction

36

- Application Scenarios for ShardingSphere LOCAL Transaction

37

#### 8.2.6 Related references

37

#### 8.2.7 Core Concept

37

- XA Protocol

37

#### 8.2.8 Limitations

37

- LOCAL Transaction

37

- XA Transaction

1.1 Introduction

Apache ShardingSphere is an ecosystem to transform any database into a distributed database system, and enhance it with sharding, elastic scaling, encryption features & more.

The project is committed to providing a multi-source heterogeneous, enhanced database platform and further building an ecosystem around the upper layer of the platform. Database Plus, the design philosophy of Apache ShardingSphere, aims at building the standard and ecosystem on the upper layer of the heterogeneous database. It focuses on how to make full and reasonable use of the computing and storage capabilities of existing databases rather than creating a brand new database. It attaches greater importance to the collaboration between multiple databases instead of the database itself.

1.1.1 ShardingSphere-JDBC

ShardingSphere-JDBC is a lightweight Java framework that provides additional services at Java’s JDBC layer.

1.1.2 ShardingSphere-Proxy

ShardingSphere-Proxy is a transparent database proxy, providing a database server that encapsulates database binary protocol to support heterogeneous languages.
### 1.2 Product Features

<table>
<thead>
<tr>
<th>Feature</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Sharding</td>
<td>Data sharding is an effective way to deal with massive data storage and computing. ShardingSphere provides a distributed database solution based on the underlying database, which can scale computing and storage horizontally.</td>
</tr>
<tr>
<td>Distributed</td>
<td>Transactional capability is key to ensuring database integrity and security and is also one of the databases’ core technologies. With a hybrid engine based on XA and BASE transactions, ShardingSphere provides distributed transaction capabilities on top of standalone databases, enabling data security across underlying data sources.</td>
</tr>
<tr>
<td>Read/write Splitting</td>
<td>Read/write splitting can be used to cope with business access with high stress. ShardingSphere provides flexible read/write splitting capabilities and can achieve read access load balancing based on the understanding of SQL semantics and the ability to perceive the underlying database topology.</td>
</tr>
<tr>
<td>Data Migration</td>
<td>Data migration is the key to connecting data ecosystems. ShardingSphere provides migration capabilities to help users migrate the data from other data sources, while simultaneously performing data sharding.</td>
</tr>
<tr>
<td>Federation</td>
<td>Federated queries are effective in utilizing data in a complex data environment. ShardingSphere provides complex data query and analysis capabilities across data sources, simplifying the data aggregation from different data locations.</td>
</tr>
<tr>
<td>Data Encryption</td>
<td>Data Encryption is a basic way to ensure data security. ShardingSphere provides a complete, transparent, secure, and low-cost data encryption solution.</td>
</tr>
<tr>
<td>Shadow Database</td>
<td>In full-link online load testing scenarios, ShardingSphere supports data isolation in complex load testing scenarios through the shadow database function. Execute your load testing scenarios in a production environment without worrying about test data polluting your production data.</td>
</tr>
</tbody>
</table>

### 1.3 Advantages

- **Ultimate Performance**
  Having been polished for years, the driver is close to a native JDBC in terms of efficiency, with ultimate performance.

- **Ecosystem Compatibility**
  The proxy can be accessed by any application using MySQL/PostgreSQL protocol, and the driver can connect to any database that implements JDBC specifications.

- **Zero Business Intrusion**
  In response to database switchover scenarios, ShardingSphere can achieve smooth business migration without business intrusion.
• Low Ops & Maintenance Cost

ShardingSphere offers a flat learning curve to DBAs and is interaction-friendly while allowing the original technology stack to remain unchanged.

• Security & Stability

It can provide enhancement capability based on mature databases while ensuring security and stability.

• Elastic Extention

It supports computing, storage, and smooth online expansion, which can meet diverse business needs.

• Open Ecosystem

It can provide users with flexibility thanks to custom systems based on multi-level (kernel, feature, and ecosystem) plugin capabilities.
ShardingSphere adopts the database plus design philosophy, which is committed to building the standards and ecology of the upper layer of the database and supplementing the missing capabilities of the database in the ecology.

**Design Philosophy: Database Plus**

- **Database Plus** is our design concept of distributed database system.
- It aims to build a standard layer and ecosystem above fragmented databases and minimize or eliminate the challenges caused by underlying databases. Guided by this concept, ShardingSphere not only links all applications and databases, but also provides enhanced capabilities such as data sharding and data encryption.
2.1 Connect: Create database upper level standard

Through flexible adaptation of database protocols, SQL dialects, and database storage, it can quickly build standards on top of multi-modal heterogeneous databases, while providing standardized connection mode for applications through built-in DistSQL.

2.2 Enhance: Database computing enhancement engine

It can further provide distributed capabilities and traffic enhancement functions based on native database capabilities. The former can break through the bottleneck of the underlying database in computing and storage, while the latter provides more diversified data application enhancement capabilities through traffic deformation, redirection, governance, authentication, and analysis.

2.3 Pluggable: Building database function ecology

The pluggable architecture of Apache ShardingSphere is composed of three layers - L1 Kernel Layer, L2 Feature Layer and L3 Ecosystem Layer.
2.3.1 L1 Kernel Layer

An abstraction of databases’ basic capabilities. All the components are required and the specific implementation method can be replaced thanks to plugins. It includes a query optimizer, distributed transaction engine, distributed execution engine, permission engine and scheduling engine.

2.3.2 L2 Feature Layer

Used to provide enhancement capabilities. All components are optional, allowing you to choose whether to include zero or multiple components. Components are isolated from each other, and multiple components can be used together by overlaying. It includes data sharding, read/write splitting, data encryption and shadow database and so on. The user-defined feature can be fully customized and extended for the top-level interface defined by Apache ShardingSphere without changing kernel codes.

2.3.3 L3 Ecosystem Layer

It is used to integrate and merge the current database ecosystems. The ecosystem layer includes database protocol, SQL parser and storage adapter, corresponding to the way in which Apache ShardingSphere provides services by database protocol, the way in which SQL dialect operates data, and the database type that interacts with storage nodes.
Apache ShardingSphere includes two independent clients: ShardingSphere-JDBC & ShardingSphere-Proxy. They all provide functions of data scale-out, distributed transaction and distributed governance, applicable in a variety of scenarios such as Java isomorphism, heterogeneous languages, and a cloud-native environment.

### 3.1 Using ShardingSphere-JDBC

ShardingSphere-JDBC is a lightweight Java framework that provides additional services at Java’s JDBC layer. With the client connecting directly to the database, it provides services in the form of jar and requires no extra deployment and dependence. It can be considered as an enhanced version of the JDBC driver, which is fully compatible with JDBC and all kinds of ORM frameworks.

- Applicable in any ORM framework based on JDBC, such as JPA, Hibernate, Mybatis, Spring JDBC Template, or direct use of JDBC;
- Support any third-party database connection pool, such as DBCP, C3P0, BoneCP, HikariCP;
- Support any kind of JDBC standard database: MySQL, PostgreSQL, Oracle, SQLServer and any JDBC adapted databases.
3.2 Using ShardingSphere-Proxy

ShardingSphere-Proxy is a transparent database proxy, providing a database server that encapsulates database binary protocol to support heterogeneous languages. Currently, MySQL and PostgreSQL protocols are provided. It can use any kind of terminal that is compatible with MySQL or PostgreSQL protocol to operate data, which is more friendly to DBAs.

- Transparent to applications, it can be used directly as MySQL/PostgreSQL;
- Compatible with MySQL-based databases, such as MariaDB, and PostgreSQL-based databases, such as openGauss;
- Applicable to any kind of client that is compatible with MySQL/PostgreSQL protocol, such as MySQL Command Client, MySQL Workbench, etc.

### 3.3 Hybrid Architecture

ShardingSphere-JDBC adopts a decentralized architecture, applicable to high-performance light-weight OLTP applications developed with Java. ShardingSphere-Proxy provides static entry and supports all languages, applicable to OLAP applications and the sharding databases management and operation situation.

Apache ShardingSphere is an ecosystem composed of multiple access ports. By combining ShardingSphere-JDBC and ShardingSphere-Proxy, and using the same registry to configure sharding strategies, it can flexibly build application systems for various scenarios, allowing architects to freely adjust the system architecture according to the current businesses.
3.3. Hybrid Architecture
Apache ShardingSphere provides two running modes: standalone mode and cluster mode.

### 4.1 Standalone Mode

It can achieve data persistence in terms of metadata information such as data sources and rules, but it is not able to synchronize metadata to multiple Apache ShardingSphere instances or be aware of each other in a cluster environment. Updating metadata through one instance causes inconsistencies in other instances because they cannot get the latest metadata.

It is ideal for engineers to build a ShardingSphere environment locally.

### 4.2 Cluster Mode

It provides metadata sharing between multiple Apache ShardingSphere instances and the capability to coordinate states in distributed scenarios.

It provides the capabilities necessary for distributed systems, such as horizontal scaling of computing capability and high availability. Clustered environments need to store metadata and coordinate nodes’ status through a separately deployed registry center.

We suggest using cluster mode in production environment.
Roadmap

1.x 2016
Sharding-JDBC
Initial version, based on a JDBC driver, and for data sharding only.

2.x 2017
To Cluster
Can coordinate in a distributed environment, with ZooKeeper as registry center.

3.x 2018
Sharding-Proxy
Using a proxy to mock a database, compatible with all programming languages and database workbenches.

4.x 2019
Apache ShardingSphere
For Apache software foundation version, change the brand, and support more databases except MySQL.

5.x 2021
To Cloud
The ShardingSphere ecosystem is expanding to include cloud solutions with Helm Charts and Operator. Operator and Helm Charts allow you to deploy ShardingSphere on Kubernetes, including services such as AWS EKS, self-hosted Kubernetes, or minikube.

To Pluggable
Micro kernel for pluggable oriented, everything is pluggable with 3 layers, add more features except sharding, such as encrypt.

To Ecosystem
Provide Database Plus production, build a standard via DistSQL, and an ecosystem with a plugin-oriented platform and features.

ShardingSphere became an Apache Top-Level Project on April 16, 2020. You are welcome to check out the mailing list and discuss via mail.
Quick Start

In shortest time, this chapter provides users with a simplest quick start with Apache ShardingSphere.

Example Codes: https://github.com/apache/shardingsphere/tree/master/examples

7.1 ShardingSphere-JDBC

7.1.1 Scenarios

There are two ways you can configure Apache ShardingSphere: Java and YAML. Developers can choose the preferred method according to their requirements.

7.1.2 Limitations

Currently only Java language is supported.

7.1.3 Requirements

The development environment requires Java JRE 8 or later.

7.1.4 Procedure

1. Rules configuration.
2. Import Maven dependency

```xml
<dependency>
    <groupId>org.apache.shardingsphere</groupId>
    <artifactId>shardingsphere-jdbc-core</artifactId>
    <version>${latest.release.version}</version>
</dependency>
```
Notice: Please change ${latest.release.version} to the actual version.

3. Create YAML configuration file

```yaml
# JDBC database name. In cluster mode, use this parameter to connect
# ShardingSphere-JDBC and ShardingSphere-Proxy.
# Default: logic_db
databaseName (?):

mode:

dataSources:

rules:
- !FOO_XXX
  ...
- !BAR_XXX
  ...

props:
  key_1: value_1
  key_2: value_2
```

4. Take spring boot as an example, edit application.properties.

```properties
# Configuring DataSource Drivers
spring.datasource.driver-class-name=org.apache.shardingsphere.driver.ShardingSphereDriver
# Specify a YAML configuration file
spring.datasource.url=jdbc:shardingsphere:classpath:xxx.yaml
```

For details, see Spring Boot.
7.2 ShardingSphere-Proxy

7.2.1 Scenarios

ShardingSphere-Proxy is positioned as a transparent database proxy. It theoretically supports any client operation data using MySQL, PostgreSQL and openGauss protocols, and is friendly to heterogeneous languages and operation and maintenance scenarios.

7.2.2 Limitations

Proxy provides limited support for system databases / tables (such as information_schema, pg_catalog). When connecting to Proxy through some graph database clients, the client or proxy may have an error prompt. You can use command-line clients (mysql, psql, gsql, etc.) to connect to the Proxy’s authentication function.
7.2.3 Requirements

Starting ShardingSphere-Proxy with Docker requires no additional dependency. To start the Proxy using binary distribution, the environment must have Java JRE 8 or higher.

7.2.4 Procedure

1. Get ShardingSphere-Proxy.

ShardingSphere-Proxy is available at: - Binary Distribution - Docker - Helm

2. Rule configuration.

Edit `%SHARDINGSphere_PROXY_HOME%/conf/server.yaml`.

Edit `%SHARDINGSphere_PROXY_HOME%/conf/config-xxx.yaml`.

   `%SHARDINGSphere_PROXY_HOME%` is the proxy extract path. For example: `/opt/shardingsphere-proxy-bin/`

Please refer to Configuration Manual for more details.

3. Import dependencies.

If the backend database is PostgreSQL or openGauss, no additional dependencies are required.

If the backend database is MySQL, please download `mysql-connector-java-5.1.49.jar` or `mysql-connector-java-8.0.11.jar` and put it into the `%SHARDINGSphere_PROXY_HOME%/ext-lib` directory.

4. Start server.

   a. Use the default configuration to start

   ```sh
   sh %SHARDINGSphere_PROXY_HOME%/bin/start.sh
   ```

   The default port is 3307, while the default profile directory is `%SHARDINGSphere_PROXY_HOME%/conf/`.

   b. Customize port and profile directory

   ```sh
   sh %SHARDINGSphere_PROXY_HOME%/bin/start.sh ${proxy_port} ${proxy_conf_directory}
   ```

   c. Force start

   ```sh
   sh %SHARDINGSphere_PROXY_HOME%/bin/start.sh -f
   ```

   Use the `-f` parameter to force start the Proxy. This parameter will ignore the abnormal data source during startup and start the Proxy forcibly. After the Proxy is started, you can remove the abnormal data source by DistSQL.

5. Use ShardingSphere-Proxy.

Use MySQL or PostgreSQL or openGauss client to connect ShardingSphere-Proxy.

Use the MySQL client to connect to the ShardingSphere-Proxy:
mysql -h${proxy_host} -P${proxy_port} -u${proxy_username} -p${proxy_password}

Use the PostgreSQL client to connect to the ShardingSphere-Proxy:

psql -h ${proxy_host} -p ${proxy_port} -U ${proxy_username}

Use the openGauss client to connect to the ShardingSphere-Proxy:

gsql -r -h ${proxy_host} -p ${proxy_port} -U ${proxy_username} -W ${proxy_password}
Apache ShardingSphere provides a variety of features, from database kernel and database distributed solution to applications closed features.

There is no boundary for these features, warmly welcome more open source engineers to join the community and provide exciting ideas and features.

## 8.1 Sharding

### 8.1.1 Background

The traditional solution that stores all the data in one concentrated node has hardly satisfied the requirement of massive data scenario in three aspects, performance, availability and operation cost.

In performance, the relational database mostly uses B+ tree index. When the data amount exceeds the threshold, deeper index will increase the disk IO access number, and thereby, weaken the performance of query. In the same time, high concurrency requests also make the centralized database to be the greatest limitation of the system.

In availability, capacity can be expanded at a relatively low cost and any extent with stateless service, which can make all the pressure, at last, fall on the database. But the single data node or simple primary-replica structure has been harder and harder to take these pressures. Therefore, database availability has become the key to the whole system.

From the aspect of operation costs, when the data in a database instance has reached above the threshold, DBA’s operation pressure will also increase. The time cost of data backup and data recovery will be more uncontrollable with increasing amount of data. Generally, it is a relatively reasonable range for the data in single database case to be within 1TB.

Under the circumstance that traditional relational databases cannot satisfy the requirement of the Internet, there are more and more attempts to store the data in native distributed NoSQL. But its incompatibility with SQL and imperfection in ecosystem block it from defeating the relational database in the competition, so the relational database still holds an unshakable position.

Sharding refers to splitting the data in one database and storing them in multiple tables and databases
according to some certain standard, so that the performance and availability can be improved. Both methods can effectively avoid the query limitation caused by data exceeding affordable threshold. What’s more, database sharding can also effectively disperse TPS. Table sharding, though cannot ease the database pressure, can provide possibilities to transfer distributed transactions to local transactions, since cross-database upgrades are once involved, distributed transactions can turn pretty tricky sometimes. The use of multiple primary-replica sharding method can effectively avoid the data concentrating on one node and increase the architecture availability.

Splitting data through database sharding and table sharding is an effective method to deal with high TPS and mass amount data system, because it can keep the data amount lower than the threshold and evacuate the traffic. Sharding method can be divided into vertical sharding and horizontal sharding.

**Vertical Sharding**

According to business sharding method, it is called vertical sharding, or longitudinal sharding, the core concept of which is to specialize databases for different uses. Before sharding, a database consists of many tables corresponding to different businesses. But after sharding, tables are categorized into different databases according to business, and the pressure is also separated into different databases. The diagram below has presented the solution to assign user tables and order tables to different databases by vertical sharding according to business need.

Vertical sharding requires to adjust the architecture and design from time to time. Generally speaking, it is not soon enough to deal with fast changing needs from Internet business and not able to really solve the single-node problem. It can ease problems brought by the high data amount and concurrency
amount, but cannot solve them completely. After vertical sharding, if the data amount in the table still exceeds the single node threshold, it should be further processed by horizontal sharding.

**Horizontal Sharding**

Horizontal sharding is also called transverse sharding. Compared with the categorization method according to business logic of vertical sharding, horizontal sharding categorizes data to multiple databases or tables according to some certain rules through certain fields, with each sharding containing only part of the data. For example, according to primary key sharding, even primary keys are put into the 0 database (or table) and odd primary keys are put into the 1 database (or table), which is illustrated as the following diagram.

Theoretically, horizontal sharding has overcome the limitation of data processing volume in single machine and can be extended relatively freely, so it can be taken as a standard solution to database sharding and table sharding.
8.1.2 Challenges

Although data sharding solves problems regarding performance, availability, and backup recovery of single points, the distributed architecture has introduced new problems while gaining benefits.

One of the major challenges is that application development engineers and database administrators become extremely overwhelmed with all these operations after such a scattered way of data sharding. They need to know from which specific sub-table can they fetch the data needed.

Another challenge is that SQL that works correctly in one single-node database does not necessarily work correctly in a sharded database. For example, table splitting results in table name changes, or incorrect handling of operations such as paging, sorting, and aggregate grouping.

Cross-library transactions are also tricky for a distributed database cluster. Reasonable use of table splitting can minimize the use of local transactions while reducing the amount of data in a single table, and appropriate use of different tables in the same database can effectively avoid the trouble caused by distributed transactions. In scenarios where cross-library transactions cannot be avoided, some businesses might still be in the need to maintain transaction consistency. The XA-based distributed transactions are not used by Internet giants on a large scale because their performance cannot meet the needs in scenarios with high concurrency, and most of them use flexible transactions with ultimate consistency instead of strong consistent transactions.

8.1.3 Goal

The main design goal of the data sharding modular of Apache ShardingSphere is to try to reduce the influence of sharding, in order to let users use horizontal sharding database group like one database.

8.1.4 Application Scenarios

Mass data high concurrency in OLTP scenarios

Most relational databases use B+ tree indexes, but when the amount of data exceeds the threshold, the increase in index depth will also increase the number of I/O in accessing the disk, which will lower the query performance. Data sharding through ShardingSphere enables data stored in a single database to be dispersed into multiple databases or tables according to a business dimension, which improves performance. The ShardingSphere-JDBC access port can meet the performance requirements of high concurrency in OLTP scenarios.
Mass data real-time analysis in OLAP scenarios

In traditional database architecture, if users want to analyze data, they need to use ETL tools first, synchronize the data to the data platform, and then perform data analysis. However, ETL tools will greatly reduce the effectiveness of data analysis. ShardingSphere-Proxy provides support for static entry and heterogeneous languages, independent of application deployment, which is suitable for real-time analysis in OLAP scenarios.

- Developer Guide: sharding

8.1.6 Core Concept

Table

Tables are a key concept for transparent data sharding. Apache ShardingSphere adapts to the data sharding requirements under different scenarios by providing diverse table types.

Logic Table

The logical name of the horizontally sharded database (table) of the same structure is the logical identifier of the table in SQL. Example: Order data is split into 10 tables according to the primary key endings, are t_order_0 to t_order_9, and their logical table names are t_order.

Actual Table

Physical tables that exist in the horizontally sharded databases. Those are, t_order_0 to t_order_9 in the previous example.

Binding Table

Refers to a set of sharded tables with consistent sharding rules. When using binding tables for multi-table associated query, a sharding key must be used for the association, otherwise, Cartesian product association or cross-library association will occur, affecting query efficiency.

For example, if the t_order table and t_order_item table are both sharded according to order_id and are correlated using order_id, the two tables are binding tables. The multi-table associated queries between binding tables will not have a Cartesian product association, so the associated queries will be much more effective. Here is an example,

If SQL is:
In the case where no binding table relationships are being set, assume that the sharding key `order_id` routes the value 10 to slice 0 and the value 11 to slice 1, then the routed SQL should be 4 items, which are presented as a Cartesian product:

```sql
SELECT i.* FROM t_order o JOIN t_order_item i ON o.order_id=i.order_id WHERE o.order_id in (10, 11);
SELECT i.* FROM t_order_0 o JOIN t_order_item_0 i ON o.order_id=i.order_id WHERE o.order_id in (10, 11);
SELECT i.* FROM t_order_0 o JOIN t_order_item_1 i ON o.order_id=i.order_id WHERE o.order_id in (10, 11);
SELECT i.* FROM t_order_1 o JOIN t_order_item_0 i ON o.order_id=i.order_id WHERE o.order_id in (10, 11);
SELECT i.* FROM t_order_1 o JOIN t_order_item_1 i ON o.order_id=i.order_id WHERE o.order_id in (10, 11);
```

After the relationships between binding tables are configured and associated with `order_id`, the routed SQL should then be 2 items:

```sql
SELECT i.* FROM t_order_0 o JOIN t_order_item_0 i ON o.order_id=i.order_id WHERE o.order_id in (10, 11);
SELECT i.* FROM t_order_1 o JOIN t_order_item_1 i ON o.order_id=i.order_id WHERE o.order_id in (10, 11);
```

The `t_order` table will be used by ShardingSphere as the master table for the entire binding table since it specifies the sharding condition. All routing calculations will use only the policy of the primary table, then the sharding calculations for the `t_order_item` table will use the `t_order` condition.

Note: multiple sharding rules in the binding table need to be configured according to the combination of logical table prefix and sharding suffix, for example:

```yaml
rules:
- !SHARDING
tables:
  t_order:
    actualDataNodes: ds_${0..1}.t_order_${0..1}
  t_order_item:
    actualDataNodes: ds_${0..1}.t_order_item_${0..1}
```

8.1. Sharding
**Broadcast data frame**

Refers to tables that exist in all data sources. The table structure and its data are identical in each database. Suitable for scenarios where the data volume is small and queries are required to be associated with tables of massive data, e.g., dictionary tables.

**Single Table**

Refers to the only table that exists in all sharded data sources. Suitable for tables with a small amount of data and do not need to be sharded.

Note: Single tables that meet the following conditions will be automatically loaded:  
- A single table showing the configuration in rules such as encrypt and mask  
- A single table created by users executing DDL statements through ShardingSphere

For other single tables that do not meet the above conditions, ShardingSphere will not automatically load them, and users can configure single table rules as needed for management.

**Data Nodes**

The smallest unit of the data shard, consists of the data source name and the real table. Example: `ds_0.t_order_0`.

The mapping relationship between the logical table and the real table can be classified into two forms: uniform distribution and custom distribution.

**Uniform Distribution**

refers to situations where the data table exhibits a uniform distribution within each data source. For example:

```
  db0
   ─── t_order0
      └── t_order1
  db1
   ─── t_order0
      └── t_order1
```

The configuration of data nodes:

```
db0.t_order0, db0.t_order1, db1.t_order0, db1.t_order1
```
Customized Distribution

Data table exhibiting a patterned distribution. For example:

```
<table>
<thead>
<tr>
<th>db0</th>
<th>t_order0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>t_order1</td>
</tr>
<tr>
<td>db1</td>
<td>t_order2</td>
</tr>
<tr>
<td></td>
<td>t_order3</td>
</tr>
<tr>
<td></td>
<td>t_order4</td>
</tr>
</tbody>
</table>
```

configuration of data nodes:

```
db0.t_order0, db0.t_order1, db1.t_order2, db1.t_order3, db1.t_order4
```

Sharding

Sharding key

A database field is used to split a database (table) horizontally. Example: If the order primary key in the order table is sharded by modulo, the order primary key is a sharded field. If there is no sharded field in SQL, full routing will be executed, of which performance is poor. In addition to the support for single-sharding fields, Apache ShardingSphere also supports sharding based on multiple fields.

Sharding Algorithm

Algorithm for sharding data, supporting =, >=, <=, >, <, BETWEEN and IN. The sharding algorithm can be implemented by the developers themselves or can use the Apache ShardingSphere built-in sharding algorithm, syntax sugar, which is very flexible.

Automatic Sharding Algorithm

Sharding algorithm—syntactic sugar is for conveniently hosting all data nodes without users having to concern themselves with the physical distribution of actual tables. Includes implementations of common sharding algorithms such as modulo, hash, range, and time.

8.1. Sharding
Customized Sharding Algorithm

Provides a portal for application developers to implement their sharding algorithms that are closely related to their business operations, while allowing users to manage the physical distribution of actual tables themselves. Customized sharding algorithms are further divided into: - Standard Sharding Algorithm Used to deal with scenarios where sharding is performed using a single key as the sharding key =, IN, BETWEEN AND, >, <, >=, <=. - Composite Sharding Algorithm Used to cope with scenarios where multiple keys are used as sharding keys. The logic containing multiple sharding keys is very complicated and requires the application developers to handle it on their own. - Hint Sharding Algorithm For scenarios involving Hint sharding.

Sharding Strategy

Consisting of a sharding key and sharding algorithm, which is abstracted independently due to the independence of the sharding algorithm. What is viable for sharding operations is the sharding key + sharding algorithm, known as sharding strategy.

Mandatory Sharding routing

For the scenario where the sharded field is not determined by SQL but by other external conditions, you can use SQL Hint to inject the shard value. Example: Conduct database sharding by employee login primary key, but there is no such field in the database. SQL Hint can be used both via Java API and SQL annotation. See Mandatory Sharding Routing for details.

Row Value Expressions

Row expressions are designed to address the two main issues of configuration simplification and integration. In the cumbersome configuration rules of data sharding, the large number of repetitive configurations makes the configuration itself difficult to maintain as the number of data nodes increases. The data node configuration workload can be effectively simplified by row expressions.

For the common sharding algorithm, using Java code implementation does not help to manage the configuration uniformly. But by writing the sharding algorithm through line expressions, the rule configuration can be effectively stored together, which is easier to browse and store.

A Row Value Expressions consists of two parts as a string, the Type Name part of the corresponding SPI implementation at the beginning of the string and the expression part.

Take `<GROOVY>t_order_${1..3}</GROOVY>` as sample, the GROOVY substring in the part of the `<GROOVY>` string is the Type Name used by the corresponding SPI implementation for this Row Value Expressions, which is identified by the `<>` symbol. And the `t_order_${1..3}` string is the expression part of this Row Value Expressions. When a Row Value Expressions does not specify a Type Name, such as `t_order_${1..3}`, the Row Value Expressions defaults to parse expressions by GROOVY implementation for InlineExpressionParser SPI.

The following sections describe the syntax rules for the GROOVY implementation.
Row expressions are very intuitive, just use \$\{ expression \} or \$\->{ expression \} in the configuration to identify the row expressions. Data nodes and sharding algorithms are currently supported. The content of row expressions uses Groovy syntax, and all operations supported by Groovy are supported by row expressions. For example:

\$\{begin..end\} denotes the range interval

\$\{[unit1, unit2, unit_x]\} denotes the enumeration value

If there are multiple \$\{ expression \} or \$\->{ expression \} expressions in a row expression, the final result of the whole expression will be a Cartesian combination based on the result of each sub-expression.

e.g. The following row expression:

\$\{["online", "offline"]\}_table\$\{1..3\}

Finally, it can be parsed as this:

online_table1, online_table2, online_table3, offline_table1, offline_table2, offline_table3

**Distributed Primary Key**

In traditional database software development, automatic primary key generation is a basic requirement. Various databases provide support for this requirement, such as self-incrementing keys of MySQL, self-incrementing sequences of Oracle, etc. After data sharding, it is very tricky to generate global unique primary keys for different data nodes. Self-incrementing keys between different actual tables within the same logical table generate repetitive primary keys because they are not mutually aware. Although collisions can be avoided by constraining the initial value and step size of self-incrementing primary keys, additional operational and maintenance rules are necessary to be introduced, rendering the solution lacking in completeness and scalability.

Many third-party solutions can perfectly solve this problem, such as UUID, which relies on specific algorithms to self-generate non-repeating keys, or by introducing primary key generation services. To facilitate users and meet their demands for different scenarios, Apache ShardingSphere not only provides built-in distributed primary key generators, such as UUID and SNOWFLAKE but also abstracts the interface of distributed primary key generators to enable users to implement their own customized self-extending primary key generators.
8.1.7 Limitations

Compatible with all commonly used SQL that routes to single data nodes; SQL routing to multiple data nodes is divided, because of complexity issues, into three conditions: stable support, experimental support, and no support.

Stable Support

Full support for DML, DDL, DCL, TCL, and common DALs. Support for complex queries such as paging, de-duplication, sorting, grouping, aggregation, table association, etc. Support SCHEMA DDL and DML statements of PostgreSQL and openGauss database. When no schema is specified in SQL, default access to ‘public’ schema. Other schemas need to declare before the table name, and do not support ‘SEARCH_PATH’ to modify the schema search path.

Normal Queries

- main statement SELECT

```
SELECT select_expr [, select_expr ...] FROM table_reference [, table_reference ...] 
[WHERE predicates]
[GROUP BY {col_name | position} [ASC | DESC], ...]
[ORDER BY {col_name | position} [ASC | DESC], ...]
[LIMIT {{offset,] row_count | row_count OFFSET offset}]
```

- select_expr

```
* | [DISTINCT] COLUMN_NAME [AS] [alias] | 
(MAX | MIN | SUM | AVG)(COLUMN_NAME | alias) [AS] [alias] | 
COUNT(*) | COLUMN_NAME | alias) [AS] [alias]
```

- table_reference

```
tbl_name [AS] alias] [index_hint_list]
| table_reference ([INNER] | {LEFT|RIGHT} [OUTER]) JOIN table_factor [JOIN ON 
conditional_expr | USING (column_list)]
```

Sub-query

Stable support is provided by the kernel when both the subquery and the outer query specify a shard key and the values of the slice key remain consistent. e.g:

```
SELECT * FROM (SELECT * FROM t_order WHERE order_id = 1) o WHERE o.order_id = 1;
```

Sub-query for pagination can be stably supported by the kernel. e.g.:
**Navigation**

- **Pagination Query**

MySQL, PostgreSQL, and openGauss are fully supported, Oracle and SQLServer are only partially supported due to more intricate paging queries.

Pagination for Oracle and SQLServer needs to be handled by subqueries, and ShardingSphere supports paging-related subqueries.

- **Oracle Support pagination by rownum**

```sql
SELECT * FROM (SELECT row_.*, rownum rownum_ FROM (SELECT * FROM t_order) row_ WHERE rownum <= ?) WHERE rownum > ?;
```

- **SQL Server Support pagination that coordinates TOP + ROW_NUMBER() OVER**

```sql
SELECT * FROM (SELECT TOP (?) ROW_NUMBER() OVER (ORDER BY o.order_id DESC) AS rownum, * FROM t_order o) AS temp WHERE temp.rownum > ? ORDER BY temp.order_id
```

Support pagination by OFFSET FETCH after SQLServer 2012

```sql
SELECT * FROM t_order o ORDER BY id OFFSET ? ROW FETCH NEXT ? ROWS ONLY
```

- **MySQL, PostgreSQL and openGauss all support LIMIT pagination without the need for sub-query:**

```sql
SELECT * FROM t_order o ORDER BY id LIMIT ? OFFSET ?
```

**Shard keys included in operation expressions**

When the sharding key is contained in an expression, the value used for sharding cannot be extracted through the SQL letters and will result in full routing.

For example, assume `create_time` is a sharding key.

```sql
SELECT * FROM t_order WHERE to_date(create_time, 'yyyy-mm-dd') = '2019-01-01';
```
LOAD DATA / LOAD XML

Support MySQL LOAD DATA and LOAD XML statements to load data to single table and broadcast table.

Experimental Support

Experimental support refers specifically to support provided by implementing Federation execution engine, an experimental product that is still under development. Although largely available to users, it still requires significant optimization.

Sub-query

The Federation execution engine provides support for subqueries and outer queries that do not both specify a sharding key or have inconsistent values for the sharding key.

e.g:

```sql
SELECT * FROM (SELECT * FROM t_order) o;
SELECT * FROM (SELECT * FROM t_order) o WHERE o.order_id = 1;
SELECT * FROM (SELECT * FROM t_order WHERE order_id = 1) o;
SELECT * FROM (SELECT * FROM t_order WHERE order_id = 1) o WHERE o.order_id = 2;
```

Cross-database Associated query

When multiple tables in an associated query are distributed across different database instances, the Federation execution engine can provide support. Assuming that t_order and t_order_item are sharded tables with multiple data nodes while no binding table rules are configured, and t_user and t_user_role are single tables distributed across different database instances, then the Federation execution engine can support the following common associated queries.

```sql
SELECT * FROM t_order o INNER JOIN t_order_item i ON o.order_id = i.order_id WHERE o.order_id = 1;
SELECT * FROM t_order o INNER JOIN t_user u ON o.user_id = u.user_id WHERE o.user_id = 1;
SELECT * FROM t_order o LEFT JOIN t_user_role r ON o.user_id = r.user_id WHERE o.user_id = 1;
SELECT * FROM t_order_item i LEFT JOIN t_user u ON i.user_id = u.user_id WHERE i.user_id = 1;
SELECT * FROM t_order_item i RIGHT JOIN t_user_role r ON i.user_id = r.user_id
```
```
WHERE i.user_id = 1;

SELECT * FROM t_user u RIGHT JOIN t_user_role r ON u.user_id = r.user_id WHERE u.user_id = 1;
```

**Do not Support**

**CASE WHEN**

The following CASE WHEN statements are not supported:
- CASE WHEN contains sub-query
- Logical names are used in CASE WHEN (Please use an alias)

**Pagination Query**

Due to the complexity of paging queries, there are currently some paging queries that are not supported for Oracle and SQLServer, such as:
- Oracle The paging method of rownum + BETWEEN is not supported at present

  - SQLServer: Currently, pagination with \(\text{WITH xxx AS (SELECT \cdots)}\) is not supported. Since the SQLServer paging statement automatically generated by Hibernate uses the \(\text{WITH}\) statement, Hibernate-based SQLServer paging is not supported at this moment. Pagination using two TOP + subquery also cannot be supported at this time.

**LOAD DATA / LOAD XML**

Not support MySQL LOAD DATA and LOAD XML statements to load data to sharding table.

**8.1.8 Appendix with SQL operator**

Limited supported SQL:

- When using `getGeneratedKeys` interface of JDBC specification to return auto-increment key, it is necessary to use a distributed key generator that supports auto-increment, and does not support other types of distributed key generators

Unsupported SQL:

- CASE WHEN contains sub-query
- Logical table names are used in CASE WHEN (Please use an alias)
- `INSERT INTO tbl_name (col1, col2, \cdots) SELECT * FROM tbl_name WHERE col3 = ?` (The `SELECT` clause does not support \* and the built-in distributed primary key generator)
- `REPLACE INTO tbl_name (col1, col2, \cdots) SELECT * FROM tbl_name WHERE col3 = ?` (The `SELECT` clause does not support \* and the built-in distributed primary key generator)
- SELECT MAX(tbl_name.col1) FROM tbl_name (If the query column is a function expression, use the table alias instead of the table name)

Other:
- You should keep actual tables, sharding columns and key generate columns in sharding rule same capitalization with tables and columns in database.

8.2 Distributed Transaction

8.2.1 Background

Database transactions should satisfy the features of ACID (atomicity, consistency, isolation and durability).
- Atomicity: transactions are executed as a whole, and either all or none is executed.
- Consistency: transactions should ensure that the state of data remains consistent after the transition.
- Isolation: when multiple transactions execute concurrently, the execution of one transaction should not affect the execution of others.
- Durability: when a transaction committed modifies data, the operation will be saved persistently.

In single data node, transactions are only restricted to the access and control of single database resources, called local transactions. Almost all the mature relational databases have provided native support for local transactions. But in distributed application situations based on micro-services, more and more of them require to include multiple accesses to services and the corresponding database resources in the same transaction. As a result, distributed transactions appear.

Though the relational database has provided perfect native ACID support, it can become an obstacle to the system performance under distributed situations. How to make databases satisfy ACID features under distributed situations or find a corresponding substitute solution, is the priority work of distributed transactions.

8.2.2 Challenge

For different application situations, developers need to reasonably weight the performance and the function between all kinds of distributed transactions.

Highly consistent transactions do not have totally the same API and functions as soft transactions, and they cannot switch between each other freely and invisibly. The choice between highly consistent transactions and soft transactions as early as development decision-making phase has sharply increased the design and development cost.

Highly consistent transactions based on XA is relatively easy to use, but is not good at dealing with long transaction and high concurrency situation of the Internet. With a high access cost, soft transactions
require developers to transform the application and realize resources lock and backward compensation.

8.2.3 Goal

The main design goal of the distributed transaction modular of Apache ShardingSphere is to integrate existing mature transaction cases to provide an unified distributed transaction interface for local transactions, 2PC transactions and soft transactions; compensate for the deficiencies of current solutions to provide a one-stop distributed transaction solution.

8.2.4 How it works

ShardingSphere provides begin/commit/rollback traditional transaction interfaces externally, and provides distributed transaction capabilities through LOCAL, XA and BASE modes.

LOCAL Transaction

LOCAL mode is implemented based on ShardingSphere’s proxy database interfaces, that is begin/commit/rollback. For a logical SQL, ShardingSphere starts transactions on each proxied database with the begin directive, executes the actual SQL, and performs commit/rollback. Since each data node manages its own transactions, there is no coordination and communication between them, and they do not know whether other data node transactions succeed or not. There is no loss in performance, but strong consistency and final consistency cannot be guaranteed.

XA Transaction

XA transaction adopts the concepts including AP(application program), TM(transaction manager) and RM(resource manager) to ensure the strong consistency of distributed transactions. Those concepts are abstracted from DTP mode which is defined by X/OPEN group. Among them, TM and RM use XA protocol to carry out both-way communication, which is realized through two-phase commit. Compared to traditional local transactions, XA transaction adds a preparation stage where the database can also inform the caller whether the transaction can be committed, in addition to passively accepting commit instructions. TM can collect the results of all branch transactions and make atomic commit at the end to ensure the strong consistency of transactions.
XA transaction is implemented based on the interface of ShardingSphere’s proxy database xa start/end/prepare/commit/rollback/recover.

For a logical SQL, ShardingSphere starts transactions in each proxied database with the xa begin directive, integrates TM internally for coordinating branch transactions, and performs xa commit/rollback. Distributed transactions based on XA protocol are more suitable for short transactions with fixed execution time because the required resources need to be locked during execution. For long transactions, data exclusivity during the entire transaction will have an impact on performance in concurrent scenarios.

**BASE Transaction**

If a transaction that implements ACID is called a rigid transaction, then a transaction based on a BASE transaction element is called a flexible transaction. BASE stands for basic availability, soft state, and eventual consistency.

- **Basically Available**: ensure that distributed transaction parties are not necessarily online at the same time.
- **Soft state**: system status updates are allowed to have a certain delay, and the delay may not be recognized by customers.
- **Eventually consistent**: guarantee the eventual consistency of the system by means of messaging.

ACID transaction puts a high demand for isolation, where all resources must be locked during the execution of transactions. Flexible transaction is to move mutex operations from the resource level to the
business level through business logic. Reduce the requirement for strong consistency in exchange for higher system throughput.

ACID-based strong consistency transactions and BASE-based final consistency transactions are not a jack of all trades and can fully leverage their advantages in the most appropriate scenarios. Apache ShardingSphere integrates the operational scheme taking SEATA as the flexible transaction. The following table can be used for comparison to help developers choose the suitable technology.

<table>
<thead>
<tr>
<th></th>
<th>LOCAL</th>
<th>XA</th>
<th>BASE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Business transformation</td>
<td>None</td>
<td>None</td>
<td>Seata server needed</td>

<td>long transaction &amp; high concurrency</td>
</tr>
</tbody>
</table>

### 8.2.5 Application Scenarios

The database’s transactions can meet ACID business requirements in a standalone application scenario. However, in distributed scenarios, traditional database solutions cannot manage and control global transactions, and users may find data inconsistency on multiple database nodes.

ShardingSphere distributed transaction makes it easier to process distributed transactions and provides flexible and diverse solutions. Users can select the distributed transaction solutions that best fit their business scenarios among LOCAL, XA, and BASE modes.

**Application Scenarios for ShardingSphere XA Transactions**

Strong data consistency is guaranteed in a distributed environment in terms of XA transactions. However, its performance may be degraded due to the synchronous blocking problem. It applies to business scenarios that require strong data consistency and low concurrency performance.

**Application Scenarios for ShardingSphere BASE Transaction**

In terms of BASE transactions, final data consistency is guaranteed in a distributed environment. Unlike XA transactions, resources are not locked during the whole transaction process, so its performance is relatively higher.
**Application Scenarios for ShardingSphere LOCAL Transaction**

In terms of LOCAL transactions, the data consistency and isolation among database nodes are not guaranteed in a distributed environment. Therefore, the business sides need to handle the inconsistencies by themselves. This applies to business scenarios where users would like to handle data inconsistency in a distributed environment by themselves.

**8.2.6 Related references**

- YAML distributed transaction configuration

**8.2.7 Core Concept**

**XA Protocol**

The original distributed transaction model of XA protocol is the “X/Open Distributed Transaction Processing (DTP)” model, XA protocol for short, which was proposed by the X/Open international consortium.

**8.2.8 Limitations**

Although Apache ShardingSphere aims at being compatible with all distributed scenario and providing the best performance, under the CAP theorem guidance, there is no sliver bullet with distributed transaction solution.

The Apache ShardingSphere community chose instead to give the users the ability to choose their preferred distributed transaction type and use the most suitable solution according to their scenarios.

**LOCAL Transaction**

**Unsupported**

- Does not support the cross-database transactions caused by network or hardware crash. For example, when updating two databases in transaction, if one database crashes before commit, then only the data of the other database can commit.
**8.2.9 Appendix with SQL operator**

Unsupported SQL:

- RAL and RDL operations of DistSQL that are used in transactions.
- DDL statements that are used in XA transactions.

Privileges required for XA transactions:

In MySQL 8, you need to grant the user XA_RECOVER_ADMIN privileges, otherwise, the XA transaction manager will report an error when executing the XA RECOVER statement.

**8.3 Readwrite-splitting**

**8.3.1 Background**

Database throughput has faced the bottleneck with increasing TPS. For the application with massive concurrency read but less write in the same time, we can divide the database into a primary database and a replica database. The primary database is responsible for the insert, delete and update of transactions, while the replica database is responsible for queries. It can significantly improve the query performance of the whole system by effectively avoiding row locks.

One primary database with multiple replica databases can further enhance processing capacity by distributing queries evenly into multiple data replicas. Multiple primary databases with multiple replica databases can enhance not only throughput but also availability. Therefore, the system can still run normally, even though any database is down or physical disk destroyed.
Different from the sharding that separates data to all nodes according to sharding keys, readwrite-splitting routes read and write separately to primary database and replica databases according SQL analysis.

Data in readwrite-splitting nodes are consistent, whereas that in shards is not. The combined use of sharding and readwrite-splitting will effectively enhance the system performance.

### 8.3.2 Challenges

Though readwrite-splitting can enhance system throughput and availability, it also brings inconsistent data, including that among multiple primary databases and among primary databases and replica databases. What’s more, it also brings the same problem as data sharding, complicating developer and operator’s maintenance and operation. The following diagram has shown the complex topological relations between applications and database groups when sharding used together with readwrite-splitting.
8.3.3 Goal

The main design goal of readwrite-splitting of Apache ShardingSphere is to try to reduce the influence of readwrite-splitting, in order to let users use primary-replica database group like one database.

8.3.4 Application Scenarios

**Complex primary-secondary database architecture**

Many systems rely on the configuration of primary-secondary database architecture to improve the throughput of the whole system. Nevertheless, this configuration can make it more complex to use services.

After accessing ShardingSphere, the read/write splitting feature can be used to manage primary-secondary databases and achieve transparent read/write splitting, enabling users to use databases with primary/secondary architecture just like using one single database.
8.3.5 Related References

Java API YAML Configuration

8.3.6 Core Concept

Primary database

The primary database is used to add, update, and delete data operations. Currently, only single primary database is supported.

Secondary database

The secondary database is used to query data operations and multi-secondary databases are supported.

Primary-Secondary synchronization

It refers to the operation of asynchronously synchronizing data from a primary database to a secondary database. Due to the asynchronism of primary-secondary synchronization, data from the primary and secondary databases may be inconsistent for a short time.

Load balancer policy

Channel query requests to different secondary databases through load balancer policy.

8.3.7 Limitations

- Data synchronization of primary and secondary databases is not supported.
- Data inconsistency resulting from data synchronization delays between primary and secondary databases is not supported.
- Multi-write of primary database is not supported.
- Transactional consistency between primary and secondary databases is not supported. In the primary-secondary model, both data reads and writes in transactions use the primary database.
8.4 DB Gateway

8.4.1 Background

With the trend of database fragmentation, using multiple types of databases together has become the norm. The scenario of using one SQL dialect to access all heterogeneous databases is increasing.

8.4.2 Challenges

The existence of diversified databases makes it difficult to standardize the SQL dialect accessing the database. Engineers need to use different dialects for different kinds of databases, and there is no unified query platform.

Automatically translate different types of database dialects into the dialects used by the database, so that engineers can use any database dialect to access all heterogeneous databases, which can reduce development and maintenance cost greatly.

8.4.3 Goal

The goal of database gateway for Apache ShardingSphere is translating SQL automatically among various databases.

8.4.4 Application Scenarios

As business scenarios and database products of enterprises become increasingly diversified, the connection between business applications and various database products becomes extremely complex. ShardingSphere database gateway can shield the connection between business applications and the underlying diversified databases. At the same time, it provides a unified access protocol and syntax system for different business scenarios, which can help enterprises quickly build a unified data access platform.

8.4.5 Core Concept

SQL Dialect

SQL dialect means database dialect, and it indicates that some database projects have their own unique syntax in addition to SQL, which are also called dialects. Different database projects may have different SQL dialects.
8.4.6 Limitations

The SQL dialect translation of Apache ShardingSphere is experimental. Currently, only MySQL/PostgreSQL dialects can be automatically translated. Engineers can use MySQL dialects and protocols to access PostgreSQL databases and vice versa.

8.5 Traffic Governance

8.5.1 Background

As the scale of data continues to expand, a distributed database has become a trend gradually. The unified management ability of cluster perspective, and control ability of individual components are necessary ability in modern database system.

8.5.2 Challenges

The challenge is ability which are unified management of centralized management, and operation in case of single node in failure.

Centralized management is to uniformly manage the state of database storage nodes and middleware computing nodes, and can detect the latest updates in the distributed environment in real time, further provide information with control and scheduling.

In the overload traffic scenario, circuit breaker and request limiting for a node to ensure whole database cluster can run continuously is a challenge to control ability of a single node.

8.5.3 Goal

The goal of Apache ShardingSphere management module is to realize the integrated management ability from database to computing node, and provide control ability for components in case of failure.

8.5.4 Application Scenarios

Overloaded compute node protection

When a compute node in a ShardingSphere cluster exceeds its load, the circuit breaker function is used to block the traffic to the compute node, to ensure that the whole cluster continues to provide stable services.
Storage node traffic limit

In the read-write splitting scenario where a storage node responsible for the read traffic in a ShardingSphere cluster receives overloaded requests, the traffic limit function is used to block traffic from compute nodes to the storage node, to ensure normal response of the storage node cluster.

8.5.5 Core Concept

Circuit Breaker

Fuse connection between Apache ShardingSphere and the database. When an Apache ShardingSphere node exceeds the max load, stop the node’s access to the database, so that the database can ensure sufficient resources to provide services for other Apache ShardingSphere nodes.

Request Limit

In the face of overload requests, open request limiting to protect some requests can still respond quickly.

8.6 Data Migration

8.6.1 Background

In a scenario where the business continues to develop and the amount of data and concurrency reaches a certain extent, the traditional single database may face problems in terms of performance, scalability and availability.

Although NoSQL solutions can solve the above problems through data sharding and horizontal scale-out, NoSQL databases generally do not support transactions and SQL.

ShardingSphere can also solve the above problems and supports data sharding and horizontal scale-out, while at the same time, also supporting distributed transactions and SQL.

The data migration scheme provided by ShardingSphere can help the traditional single database smoothly switch to ShardingSphere.

8.6.2 Challenges

The data migration process should not affect the running services. So the first challenge is to minimize the time window during which data is not available.

Next, data migration should not affect existing data. So the second challenge is to ensure the data correctness.
8.6.3 Goal

The major goal of Apache ShardingSphere in performing data migration is to reduce the impact of data migration on services and provide a one-stop universal data migration solution.

8.6.4 Application Scenarios

Application scenario one: when an application system is using a traditional single database, and the amount of data in a single table reaches 100 million and is still growing rapidly, a single database that continues to run with a high load will become the bottleneck of the system.

Once the database becomes the bottleneck, it is useless to scale out the application server. Instead, it is the database that needs to be scaled out.

8.6.5 Related References

- Configurations of data migration
- Reference of data migration

8.6.6 Core Concept

Nodes

Instances for running compute or storage tier component processes. These can either be physical machines, virtual machines, or containers, etc.

Cluster

Multiple nodes that are assembled together to provide a specified service.

Source

The storage cluster where the original data resides.

Target

The target storage cluster to which the original data is to be migrated.
Data Migration Process

The entire process of replicating data from one storage cluster to another.

Stock Data

The data that was already in the data node before the data migration operation started.

Incremental Data

New data generated by operational systems during the execution of data migration operations.

8.6.7 Limitations

Procedures Supported

• Migration of peripheral data to databases managed by Apache ShardingSphere.
• Target proxy without rule or configure any rule.
• Migration of single column primary key or unique key table, the first column type could be: integer data type, string data type and part of binary data type (e.g. MySQL VARBINARY).
• Migration of multiple column primary keys or unique keys table.

Procedures not supported

• Migration on top of the current storage node is not supported, so a brand new database cluster needs to be prepared as the migration target cluster.
• Target proxy table rule contains HINT strategy.
• Use different target table schema from source table schema.
• Source table DDL changes during migration.

8.7 Encryption

8.7.1 Background

Security control has always been a crucial link of data governance, data encryption falls into this category. For both Internet enterprises and traditional sectors, data security has always been a highly valued and sensitive topic. Data encryption refers to transforming some sensitive information through encrypt rules to safely protect the private data. Data involves client’s security or business sensibility, such as ID number, phone number, card number, client number and other personal information, requires data encryption according to relevant regulations.
For data encryption requirements, there are the following situations in realistic business scenarios:

- When the new business start to launch, and the security department stipulates that the sensitive information related to users, such as banks and mobile phone numbers, should be encrypted and stored in the database, and then decrypted when used.

### 8.7.2 Challenges

In the real business scenario, the relevant business development team often needs to implement and maintain a set of encryption and decryption system according to the needs of the company’s security department. When the encryption scenario changes, the encryption system often faces the risk of reconstruction or modification. In addition, for the online business system, it is relatively complex to realize seamless encryption transformation with transparency, security and low risk without modifying the business logic and SQL.

### 8.7.3 Goal

Provides a security and transparent data encryption solution, which is the main design goal of Apache ShardingSphere data encryption module.

### 8.7.4 Application Scenarios

For scenarios requiring the quick launch of new services while respecting encryption regulations. The ShardingSphere encryption feature can be used to quickly achieve compliant data encryption, without requiring users to develop complex encryption systems.

At the same time, its flexibility can also help users avoid complex rebuilding and modification risks caused by encryption scenario changes.

### 8.7.5 Related References

- Configuration: Data Encryption
- Developer Guide: Data Encryption

### 8.7.6 Core Concept

**Logic column**

It is used to calculate the encryption and decryption columns and it is the logical identifier of the column in SQL. Logical columns contain ciphertext columns (mandatory), query-helper columns (optional), like-query columns (optional), and plaintext columns (optional).
Cipher column

Encrypted data columns.

Assisted query column

It is a helper column used for queries. For some non-idempotent encryption algorithms with higher security levels, irreversible idempotent columns are provided for queries.

Like query column

It is a helper column used for like queries.

8.7.7 Limitations

- You need to process the original data on stocks in the database by yourself.
- The `like` query supports `%`, `_`, but currently does not support escape.
- Case insensitive queries are not supported for the encrypted fields.
- Comparison operations are not supported for encrypted fields, such as `GREATER THAN`, `LESS THAN`, `ORDER BY`, `BETWEEN`.
- Calculation operations are not supported for encrypted fields, such as `AVG`, `SUM`, and computation expressions.
- When projection subquery contains encrypt column, you must use alias.

8.7.8 Appendix with SQL operator

Unsupported SQL:

- The case-insensitive queries are not supported by encrypted fields.
- Comparison operations are not supported for encrypted fields, such as `GREATER THAN`, `LESS THAN`, `ORDER BY`, `BETWEEN`.
- Calculation operations are not supported for encrypted fields, such as `AVG`, `SUM`, and computation expressions.
- SQL that contains encrypt column in subquery and uses asterisks for outer projection is not supported.

Other:

- You should keep encrypt columns, assisted columns and like columns in encrypt rule same capitalization with columns in database.
8.8 Data Masking

8.8.1 Background

With the introduction of laws on user data protection, the protection of personal privacy data has risen to the legal level. Traditional application systems generally lack protection measures for personal privacy data. Data masking can achieve special encryption, masking and replacement of the data returned by the production database according to user-defined masking rules without any changes to the data in the production database to ensure the sensitivity of the production environment data can be protected.

8.8.2 Challenges

In real business scenarios, relevant DevOps teams often need to implement and maintain a set of masking functions by themselves according to data masking requirements, and the masking functions are often coupled in various business logics. Additionally different business systems are difficult to reuse. When the masking scenario changes, the masking function maintained by itself often faces the risk of refactoring or modification.

8.8.3 Goal

According to industry needs for data masking and the pain points of business transformation, it provides a complete, safe, transparent, and low transformation cost data masking integration solution, which is the main design goal of the Apache ShardingSphere data masking module.

8.8.4 Application Scenarios

Whether it is a new business that is launched quickly or a mature business that has already been launched, you can access the data masking function of ShardingSphere to quickly complete the configuration of mask rules. Customers can use data masking function transparently without developing a masking function coupled to the business system, and without changing any business logic and SQL.

8.8.5 Related References

- Configuration: Data Mask
- Developer Guide: Data Mask
8.8.6 Core Concept

Logic column

The logical name used to calculate masked column, which is logical identifier of column in SQL.

8.8.7 Limitations

- Masked columns only support string types, not other non-string types.

8.9 Shadow

8.9.1 Background

Under the distributed application architecture based on microservices, business requires multiple services to be completed through a series of services and middleware calls. The pressure testing of a single service can no longer reflect the real scenario.

In the test environment, the cost of rebuild complete set of pressure test environment similar to the production environment is too high. It is usually impossible to simulate the complexity and data of the production environment.

So, it is the better way to use the production environment for pressure test. The test results obtained real capacity and performance of the system accurately.

8.9.2 Challenges

Pressure testing on production environment is a complex and huge task. Coordination and adjustments between microservices and middlewares required to cope with the transparent transmission of different flow rates and pressure test tags. Usually we will build a complete set of pressure testing platform for different test plans.

Data isolation have to be done at the database-level, in order to ensure the reliability and integrity of the production data, data generated by pressure testing routed to test database. Prevent test data from polluting the real data in the production database.

This requires business applications to perform data classification based on the transparently transmitted pressure test identification before executing SQL, and route the corresponding SQL to the corresponding data source.
8.9.3 Goal

Apache ShardingSphere focuses on data solutions in pressure testing on production environment. The main goal of the Apache ShardingSphere shadow Database module is routing pressure testing data to user defined database automatically.

8.9.4 Application Scenario

In order to improve the accuracy of stress testing and reduce the testing cost under the distributed application architecture based on microservices, stress testing is usually carried out in production environments, which will notably increase testing risks. However, the ShardingSphere shadow DB function, combined with the flexible configuration of the shadow algorithm, can address data pollution, improve database performance, and meet the requirements of online stress testing in complex business scenarios.

8.9.5 Related References

- Java API: shadow DB
- YAML configuration: shadow DB

8.9.6 Core Concept

Production Database

Database for production data

Shadow Database

The Database for stress test data isolation. Configurations should be the same as the Production Database.

Shadow Algorithm

Shadow Algorithm, which is closely related to business operations, currently has 2 types.

- Column based shadow algorithm Routing to shadow database by recognizing data from SQL. Suitable for stress test scenario that has an emphasis on data list.
- Hint based shadow algorithm Routing to shadow database by recognizing comments from SQL. Suitable for stress test driven by the identification of upstream system passage.
8.9.7 Limitations

Hint based shadow algorithm

No

Column based shadow algorithm

Does not support DDL.

Does not support scope, group, subqueries such as BETWEEN, GROUP BY … HAVING, etc.

SQL support list

- INSERT

<table>

8.10 Observability

8.10.1 Background

In order to grasp the distributed system status, observe running state of the cluster is a new challenge. The point-to-point operation mode of logging in to a specific server cannot suite to large number of distributed servers. Telemetry through observable data is the recommended operation and maintenance
mode for them. Tracking, metrics and logging are important ways to obtain observable data of system status.

APM (application performance monitoring) is to monitor and diagnose the performance of the system by collecting, storing and analyzing the observable data of the system. Its main functions include performance index monitoring, call stack analysis, service topology, etc.

Apache ShardingSphere is not responsible for gathering, storing and demonstrating APM data, but provides the necessary information for the APM. In other words, Apache ShardingSphere is only responsible for generating valuable data and submitting it to relevant systems through standard protocols or plug-ins. Tracing is to obtain the tracking information of SQL parsing and SQL execution. Apache ShardingSphere provides support for OpenTelemetry, SkyWalking by default. It also supports users to develop customized components through plug-in.

- Use OpenTelemetry OpenTelemetry was merged by OpenTracing and OpenCensus in 2019. In this way, you only need to fill in the appropriate configuration in the agent configuration file according to OpenTelemetry SDK Autoconfigure Guide. Data can be exported to Jaeger, Zipkin.

- Use SkyWalking Enable the SkyWalking plug-in in configuration file and need to configure the SkyWalking apm-toolkit.

- Use SkyWalking’s automatic monitor probe Cooperating with Apache SkyWalking team, Apache ShardingSphere team has realized ShardingSphere automatic monitor probe to automatically send performance data to SkyWalking. Note that automatic probe in this way cannot be used together with Apache ShardingSphere plug-in probe.

Metrics used to collect and display statistical indicator of cluster. Apache ShardingSphere supports Prometheus by default.
8.10.2 Challenges

Tracing and metrics need to collect system information through event tracking. Lots of events tracking make kernel code mess, difficult to maintain, and difficult to customize extend.

8.10.3 Goal

The goal of Apache ShardingSphere observability module is providing as many performance and statistical indicators as possible and isolating kernel code and embedded code.
8.10.4 Application Scenarios

ShardingSphere provides observability for applications through the Agent module, and this feature applies to the following scenarios:

**Monitoring panel**

The system’s static information (such as application version) and dynamic information (such as the number of threads and SQL processing information) are exposed to a third-party application (such as Prometheus) using a standard interface. Administrators can visually monitor the real-time system status.

**Monitoring application performance**

In ShardingSphere, a SQL statement needs to go through the processes of parsing, routing, rewriting, execution, and result merging before it is finally executed and the response can be output. If a SQL statement is complex and the overall execution takes a long time, how do we know which procedure has room for optimization?

Through Agent plus Tracing, administrators can learn about the time consumption of each step of SQL execution. Thus, they can easily locate performance risks and formulate targeted SQL optimization schemes.

**Tracing application links**

In a distributed application plus data sharding scenario, it is tricky to figure out which node the SQL statement is issued from and which data source the statement is finally executed on. If an exception occurs during SQL execution, how do we locate the node where the exception occurred?

Agent + Tracing can help users solve the above problems.

Through tracing the full link of the SQL execution process, users can get complete information such as “where the SQL comes from and where it is sent to”.

They can also visually observe the SQL routing situation through the generated topological graph, make timely responses, and quickly locate the root cause of problems.

8.10.6 Core Concept

Agent

Based on bytecode enhancement and plugin design to provide tracing, metrics and logging features. Only after the plugin of the Agent is enabled, the monitoring indicator data can be output to the third-party APM for display.

APM

APM is an acronym for Application Performance Monitoring. Focusing on the performance diagnosis of distributed systems, its main functions include call chain display, application topology analysis, etc.

Tracing

Tracing data between distributed services or internal processes will be collected by agent. It will then be sent to third-party APM systems.

Metrics

System statistical indicators are collected through probes for display by third-party applications.

Logging

The log can be easily expanded through the agent to provide more information for analyzing the system running status.
This chapter describes how to use projects of Apache ShardingSphere.

### 9.1 ShardingSphere-JDBC

Configuration is the only module in ShardingSphere-JDBC that interacts with application developers, through which developers can quickly and clearly understand the functions provided by ShardingSphere-JDBC.

This chapter is a configuration manual for ShardingSphere-JDBC, which can also be referred to as a dictionary if necessary.

ShardingSphere-JDBC has provided 2 kinds of configuration methods for different situations. By configuration, application developers can flexibly use data sharding, readwrite-splitting, data encryption, shadow database or the combination of them.

Mixed rule configurations are very similar to single rule configuration, except for the differences from single rule to multiple rules.

It should be noted that the superposition between rules are data source and table name related. If the previous rule is data source oriented aggregation, the next rule needs to use the aggregated logical data source name configured by the previous rule when configuring the data source; Similarly, if the previous rule is table oriented aggregation, the next rule needs to use the aggregated logical table name configured by the previous rule when configuring the table.

Please refer to Example for more details.
9.1.1 YAML Configuration

Overview

YAML configuration provides interaction with ShardingSphere JDBC through configuration files. When used with the governance module together, the configuration of persistence in the configuration center is YAML format.

Note: The YAML configuration file supports more than 3MB of configuration content.

YAML configuration is the most common configuration mode, which can omit the complexity of programming and simplify user configuration.

Usage

Import Maven Dependency

```xml
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-jdbc-core</artifactId>
  <version>${shardingsphere.version}</version>
</dependency>
```

YAML Format

ShardingSphere-JDBC YAML file consists of database name, mode configuration, data source map, rule configurations and properties.

Note: The example connection pool is HikariCP, which can be replaced with other connection pools according to business scenarios.

```yaml
# JDBC logic database name. Through this parameter to connect ShardingSphere-JDBC
and ShardingSphere-Proxy.
# Default value: logic_db
databaseName (?):

mode:

dataSources:

rules:
- !FOO_XXX
  ...
- !BAR_XXX
  ...

props:
```
Create Data Source

The ShardingSphereDataSource created by YamlShardingSphereDataSourceFactory implements the standard JDBC DataSource interface.

```java
File yamlFile = // Indicate YAML file
DataSource dataSource = YamlShardingSphereDataSourceFactory.createDataSource(yamlFile);
```

Use Data Source

Same with Java API.

YAML Syntax Explanation

!! means instantiation of that class
!
 means self-defined alias
- means one or multiple can be included
[] means array, can substitutable with - each other

Mode

Parameters

```yaml
data
   mode (?): # Default value is Standalone
   type: # Type of mode configuration. Values could be: Standalone, Cluster
   repository (?): # Persist repository configuration
```

Please refer to Mode Configuration for more mode details.

Please refer to DataSource Configuration for more data source details.

Please refer to Rules Configuration for more rule details.
Standalone Mode

mode:
  type: Standalone
  repository:
    type: # Type of persist repository
    props: # Properties of persist repository
      foo_key: foo_value
      bar_key: bar_value

Cluster Mode (recommended)

mode:
  type: Cluster
  repository:
    type: # Type of persist repository
    props: # Properties of persist repository
      namespace: # Namespace of registry center
      server-lists: # Server lists of registry center
      foo_key: foo_value
      bar_key: bar_value

Notes

1. Cluster mode deployment is recommended for production environment.
2. The ZooKeeper registry center is recommended for cluster mode deployment.
3. If there is configuration information in the ZooKeeper, please refer to the config information there.

Sample

Standalone Mode

mode:
  type: Standalone
  repository:
    type: JDBC
Cluster Mode (recommended)

mode:
  type: Cluster
  repository:
    type: ZooKeeper
    props:
      namespace: governance
      server-lists: localhost:2181
      retryIntervalMilliseconds: 500
      timeToLiveSeconds: 60

Using the persistent repository requires additional introduction of the corresponding Maven dependencies. It is recommended to use:

```xml
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-cluster-mode-repository-zookeeper</artifactId>
  <version>${shardingsphere.version}</version>
</dependency>
```

Related References

- Installation and Usage of ZooKeeper Registry Center
- Please refer to Builtin Persist Repository List for more details about the type of repository.
- Please refer to ShardingSphere-JDBC Optional Plugins for more implementations of the persistent repository.

DataSource

Background

ShardingSphere-JDBC Supports all JDBC drivers and data source connection pools.

In this example, the database driver is MySQL, and the connection pool is HikariCP, which can be replaced with other database drivers and connection pools. When using ShardingSphere JDBC, the property name of the JDBC pool depends on the definition of the respective JDBC pool and is not defined by ShardingSphere. For related processing, please refer to the class `org.apache.shardingsphere.infra.datasource.pool.creator.DataSourcePoolCreator`. For example, with Alibaba Druid 1.2.9, using url instead of jdbcUrl in the example below is the expected behavior.
Parameters

dataSources: # Data sources configuration, multiple <data-source-name> available

  <data_source_name>: # Data source name
    dataSourceClassName: # Data source class name
    driverClassName: # The database driver class name is subject to the
    configuration of the data source connection pool itself
    jdbcUrl: # The database URL connection is subject to the configuration of the
data source connection pool itself
    username: # Database username, subject to the configuration of the data source
    connection pool itself
    password: # The database password is subject to the configuration of the data
    source connection pool itself
    # ... Other properties of data source pool

Sample

dataSources:
  ds_1:
    dataSourceClassName: com.zaxxer.hikari.HikariDataSource
    driverClassName: com.mysql.jdbc.Driver
    jdbcUrl: jdbc:mysql://localhost:3306/ds_1
    username: root
    password:
  ds_2:
    dataSourceClassName: com.zaxxer.hikari.HikariDataSource
    driverClassName: com.mysql.jdbc.Driver
    jdbcUrl: jdbc:mysql://localhost:3306/ds_2
    username: root
    password:

  # Configure other data sources
Rules

Rules are pluggable part of Apache ShardingSphere. This chapter is a YAML rule configuration manual for ShardingSphere-JDBC.

Sharding

Background

Data sharding YAML configuration is highly readable. The dependencies between sharding rules can be quickly understood through the YAML format. ShardingSphere automatically creates the ShardingSphereDataSource object according to YAML configuration, which can reduce unnecessary coding for users.

Parameters

```yaml
rules:
  - !SHARDING
    tables: # Sharding table configuration
      <logic_table_name> (+): # Logic table name
        actualDataNodes (?): # Describe data source names and actual tables (refer to Inline syntax rules)
        databaseStrategy (?): # Databases sharding strategy, use default databases sharding strategy if absent. sharding strategy below can choose only one.
          standard: # For single sharding column scenario
            shardingColumn: # Sharding column name
            shardingAlgorithmName: # Sharding algorithm name
          complex: # For multiple sharding columns scenario
            shardingColumns: # Sharding column names, multiple columns separated with comma
            shardingAlgorithmName: # Sharding algorithm name
          hint: # Sharding by hint
            shardingAlgorithmName: # Sharding algorithm name
          none: # Do not sharding
            tableStrategy: # Tables sharding strategy, same as database sharding strategy
            keyGenerateStrategy: # Key generator strategy
              column: # Column name of key generator
              keyGeneratorName: # Key generator name
            auditStrategy: # Sharding audit strategy
              auditorNames: # Sharding auditor name
                - <auditor_name>
                - <auditor_name>
              allowHintDisable: true # Enable or disable sharding audit hint
            autoTables: # Auto Sharding table configuration
              t_order_auto: # Logic table name
              actualDataSources (?): # Data source names
```

9.1. ShardingSphere-JDBC
Trying to read the document naturally:

```yaml
shardingStrategy: # Sharding strategy
  standard: # For single sharding column scenario
    shardingColumn: # Sharding column name
      shardingAlgorithmName: # Auto sharding algorithm name
    bindingTables (+): # Binding tables
      - <logic_table_name_1, logic_table_name_2, ...>
        - <logic_table_name_1, logic_table_name_2, ...>
    defaultDatabaseStrategy: # Default strategy for database sharding
    defaultTableStrategy: # Default strategy for table sharding
    defaultKeyGenerateStrategy: # Default Key generator strategy
    defaultShardingColumn: # Default sharding column name

# Sharding algorithm configuration
shardingAlgorithms:
  <sharding_algorithm_name> (+): # Sharding algorithm name
    type: # Sharding algorithm type
    props: # Sharding algorithm properties
    # ...

# Key generate algorithm configuration
keyGenerators:
  <key_generate_algorithm_name> (+): # Key generate algorithm name
    type: # Key generate algorithm type
    props: # Key generate algorithm properties
    # ...

# Sharding audit algorithm configuration
auditors:
  <sharding_audit_algorithm_name> (+): # Sharding audit algorithm name
    type: # Sharding audit algorithm type
    props: # Sharding audit algorithm properties
    # ...

- !BROADCAST
  tables: # Broadcast tables
    - <table_name>
    - <table_name>
```

**Procedure**

1. Configure data sharding rules in YAML files, including data source, sharding rules, and global attributes and other configuration items.

2. Call `createDataSource` method of the object `YamlShardingSphereDataSourceFactory`. Create `ShardingSphereDataSource` according to the configuration information in YAML files.

---

**9.1. ShardingSphere-JDBC** 64
The YAML configuration sample of data sharding is as follows:

```yaml
dataSources:
  ds_0:
    dataSourceClassName: com.zaxxer.hikari.HikariDataSource
    driverClassName: com.mysql.jdbc.Driver
    jdbcUrl: jdbc:mysql://localhost:3306/demo_ds_0?serverTimezone=UTC&useSSL=false&useUnicode=true&characterEncoding=UTF-8
    username: root
    password:
  ds_1:
    dataSourceClassName: com.zaxxer.hikari.HikariDataSource
    driverClassName: com.mysql.jdbc.Driver
    jdbcUrl: jdbc:mysql://localhost:3306/demo_ds_1?serverTimezone=UTC&useSSL=false&useUnicode=true&characterEncoding=UTF-8
    username: root
    password:

rules:
- !SHARDING
  tables:
    t_order:
      actualDataNodes: ds_${0..1}.t_order_${0..1}
      tableStrategy:
        standard:
          shardingColumn: order_id
          shardingAlgorithmName: t_order_inline
      keyGenerateStrategy:
        column: order_id
        keyGeneratorName: snowflake
      auditStrategy:
        auditorNames:
          - sharding_key_required_auditor
        allowHintDisable: true
    t_order_item:
      actualDataNodes: ds_${0..1}.t_order_item_${0..1}
      tableStrategy:
        standard:
          shardingColumn: order_id
          shardingAlgorithmName: t_order_item_inline
      keyGenerateStrategy:
        column: order_item_id
        keyGeneratorName: snowflake
    t_account:
      actualDataNodes: ds_${0..1}.t_account_${0..1}
      tableStrategy:
        standard:
```

9.1. ShardingSphere-JDBC
shardingAlgorithmName: t_account_inline
keyGenerateStrategy:
  column: account_id
  keyGeneratorName: snowflake
defaultShardingColumn: account_id
bindingTables:
  - t_order,t_order_item
defaultDatabaseStrategy:
  standard:
    shardingColumn: user_id
    shardingAlgorithmName: database_inline
defaultTableStrategy:
  none:

shardingAlgorithms:
  database_inline:
    type: INLINE
    props:
      algorithm-expression: ds_${user_id % 2}
  t_order_inline:
    type: INLINE
    props:
      algorithm-expression: t_order_${order_id % 2}
  t_order_item_inline:
    type: INLINE
    props:
      algorithm-expression: t_order_item_${order_id % 2}
  t_account_inline:
    type: INLINE
    props:
      algorithm-expression: t_account_${account_id % 2}
keyGenerators:
  snowflake:
    type: SNOWFLAKE
auditors:
  sharding_key_required_auditor:
    type: DML_SHARDING_CONDITIONS

- !BROADCAST
tables: # Broadcast tables
  - t_address
  props:
    sql-show: false

Read the YAML configuration to create a data source according to the createDataSource method of YamlShardingSphereDataSourceFactory.
YamlShardingSphereDataSourceFactory.createDataSource(getFile("/META-INF/sharding-databases-tables.yaml"));

Broadcast Table

Background

Broadcast table YAML configuration is highly readable. The broadcast rules can be quickly understood thanks to the YAML format. ShardingSphere automatically creates the ShardingSphereDataSource object according to the YAML configuration, which reduces unnecessary coding for users.

Parameters

rules:
- !BROADCAST
tables: # Broadcast tables
  - <table_name>
  - <table_name>

Procedure

1. Configure broadcast table list in the YAML file.
2. Call the createDataSource method of the object YamlShardingSphereDataSourceFactory. Create ShardingSphereDataSource according to the configuration information in YAML files.

Sample

The YAML configuration sample of the broadcast table is as follows:

dataSources:
  ds_0:
    dataSourceClassName: com.zaxxer.hikari.HikariDataSource
driverClassName: com.mysql.jdbc.Driver
    jdbcUrl: jdbc:mysql://localhost:3306/demo_ds_0?serverTimezone=UTC&useSSL=false&
    useUnicode=true&characterEncoding=UTF-8
    username: root
password:

ds_1:
   dataSourceClassName: com.zaxxer.hikari.HikariDataSource
driverClassName: com.mysql.jdbc.Driver
jdbcUrl: jdbc:mysql://localhost:3306/demo_ds_1?serverTimezone=UTC&useSSL=false&useUnicode=true&characterEncoding=UTF-8
   username: root
   password:

rules:
- !BROADCAST
  tables:
    - t_address

Read the YAML configuration to create a data source according to the createDataSource method of YamlShardingSphereDataSourceFactory.

YamlShardingSphereDataSourceFactory.createDataSource(getFile("/META-INF/broadcast-databases-tables.yaml"));

Readwrite-splitting

Background

Read/write splitting YAML configuration is highly readable. The YAML format enables you to quickly understand the dependencies between read/write sharding rules. ShardingSphere automatically creates the ShardingSphereDataSource object according to the YAML configuration, which reduces unnecessary coding for users.

Parameters

Readwrite-splitting

rules:
- !READWRITE_SPLITTING
dataSources:
  <data_source_name> (+): # Logic data source name of readwrite-splitting, which uses Groovy's Row Value Expressions SPI implementation to parse by default
    write_data_source_name: # Write data source name, which uses Groovy's Row Value Expressions SPI implementation to parse by default
    read_data_source_names: # Read data source names, multiple data source names separated with comma, which uses Groovy's Row Value Expressions SPI implementation to parse by default
    transactionalReadQueryStrategy (?): # Routing strategy for read query within a transaction, values include: PRIMARY (to primary), FIXED (to fixed data source),

9.1. ShardingSphere-JDBC 68
DYNAMIC (to any data source), default value: DYNAMIC
  loadBalancerName: # Load balance algorithm name

  # Load balance algorithm configuration
  loadBalancers:
    <load_balancer_name> (+): # Load balance algorithm name
      type: # Load balance algorithm type
      props: # Load balance algorithm properties
        # ...

Please refer to Built-in Load Balance Algorithm List for more details about type of algorithm.

Procedure

1. Add read/write splitting data source.
2. Set the load balancer algorithm.
3. Use read/write data source.

Sample

    rules:
    - !READWRITE_SPLITTING
      dataSources:
        readwrite_ds:
          writeDataSourceName: write_ds
          readDataSourceNames:
            - read_ds_0
            - read_ds_1
          transactionalReadQueryStrategy: PRIMARY
          loadBalancerName: random
      loadBalancers:
        random:
          type: RANDOM

- Java API: read-write splitting
Distributed Transaction

Background

ShardingSphere provides three modes for distributed transactions LOCAL, XA, BASE.

Parameters

```yaml
transaction:
  defaultType: # Transaction mode, optional value LOCAL/XA/BASE
  providerType: # Specific implementation of the mode
```

Procedure

Use LOCAL Mode

The content of the server.yaml configuration file is as follows:

```yaml
transaction:
  defaultType: LOCAL
```

Use XA Mode

The content of the server.yaml configuration file is as follows:

```yaml
transaction:
  defaultType: XA
  providerType: Narayana/Atomikos
```

To manually add Narayana-related dependencies:

- jta-5.12.4.Final.jar
- arjuna-5.12.4.Final.jar
- common-5.12.4.Final.jar
- jboss-connector-api_1.7_spec-1.0.0.Final.jar
- jboss-logging-3.2.1.Final.jar
- jboss-transaction-api_1.2_spec-1.0.0.Alpha3.jar
- jboss-transaction-spi-7.6.0.Final.jar
- narayana-jts-integration-5.12.4.Final.jar
- shardingsphere-transaction-xa-narayana-x.x.x-SNAPSHOT.jar
Use BASE Mode

The content of the server.yaml configuration file is as follows:

```yaml
transaction:
  defaultType: BASE
  providerType: Seata
```

Build a Seata Server, add relevant configuration files and Seata dependencies, see ShardingSphere Integrates Seata Flexible Transactions

Encryption

Background

The YAML configuration approach to data encryption is highly readable, with the YAML format enabling a quick understanding of dependencies between encryption rules. Based on the YAML configuration, ShardingSphere automatically completes the creation of ShardingSphereDataSource objects, reducing unnecessary coding efforts for users.

Parameters

```yaml
rules:
- !ENCRYPT
tables:
  <table_name> (+): # Encrypt table name
    columns:
      <column_name> (+): # Encrypt logic column name
        cipher:
          name: # Cipher column name
          encryptorName: # Cipher encrypt algorithm name
          assistedQuery (?):
            name: # Assisted query column name
            encryptorName: # Assisted query encrypt algorithm name
          likeQuery (?):
            name: # Like query column name
            encryptorName: # Like query encrypt algorithm name

  # Encrypt algorithm configuration
  encryptors:
    <encrypt_algorithm_name> (+): # Encrypt algorithm name
      type: # Encrypt algorithm type
      props: # Encrypt algorithm properties
      # ...
```

Please refer to Built-in Encrypt Algorithm List for more details about type of algorithm.
Procedure

1. Configure data encryption rules in the YAML file, including data sources, encryption rules, global attributes, and other configuration items.

2. Using the `createDataSource` of calling the `YamlShardingSphereDataSourceFactory` object to create `ShardingSphereDataSource` based on the configuration information in the YAML file.

Sample

The data encryption YAML configurations are as follows:

```yaml
dataSources:
  unique_ds:
    dataSourceClassName: com.zaxxer.hikari.HikariDataSource
driverClassName: com.mysql.jdbc.Driver
username: root
password:
rules:
- !ENCRYPT
tables:
  t_user:
    columns:
      username:
        cipher:
          name: username
          encryptorName: aes_encryptor
        assistedQuery:
          name: assisted_query_username
          encryptorName: assisted_encryptor
        likeQuery:
          name: like_query_username
          encryptorName: like_encryptor
      pwd:
        cipher:
          name: pwd
          encryptorName: aes_encryptor
        assistedQuery:
          name: assisted_query_pwd
          encryptorName: assisted_encryptor
encryptors:
  aes_encryptor:
    type: AES
    props:
      aes-key-value: 123456abc
```
Read the YAML configuration to create a data source according to the createDataSource method of YamlShardingSphereDataSourceFactory.

YamlShardingSphereDataSourceFactory.createDataSource(getFile());

In order to keep compatibility with earlier YAML configuration, ShardingSphere provides following compatible configuration through ‘COMPATIBLE_ENCRYPT’, which will be removed in future versions, and it is recommended to upgrade latest YAML configuration.

dataSources:
  unique_ds:
    dataSourceClassName: com.zaxxer.hikari.HikariDataSource
driverClassName: com.mysql.jdbc.Driver
    username: root
    password:

rules:
- !COMPATIBLE_ENCRYPT
  tables:
    t_user:
      columns:
        username:
          cipherColumn: username
          encryptorName: aes_encryptor
          assistedQueryColumn: assisted_query_username
          assistedQueryEncryptorName: assisted_encryptor
          likeQueryColumn: like_query_username
          likeQueryEncryptorName: like_encryptor
        pwd:
          cipherColumn: pwd
          encryptorName: aes_encryptor
          assistedQueryColumn: assisted_query_pwd
          assistedQueryEncryptorName: assisted_encryptor

encryptors:
aes_encryptor:
  type: AES
  props:
    aes-key-value: 123456abc
assisted_encryptor:
  type: MD5
  like_encryptor:
The YAML configuration approach to data masking is highly readable, with the YAML format enabling a quick understanding of dependencies between mask rules. Based on the YAML configuration, ShardingSphere automatically completes the creation of ShardingSphereDataSource objects, reducing unnecessary coding efforts for users.

**Parameters**

```yaml
rules:
  - !MASK
tables:
    <table_name> (+): # Mask table name
columns:
    <column_name> (+): # Mask logic column name
    maskAlgorithm: # Mask algorithm name

# Mask algorithm configuration
maskAlgorithms:
  <mask_algorithm_name> (+): # Mask algorithm name
type: # Mask algorithm type
props: # Mask algorithm properties
  # ...

Please refer to Built-in Mask Algorithm List for more details about type of algorithm.
```
Procedure

1. Configure data masking rules in the YAML file, including data sources, mask rules, global attributes, and other configuration items.

2. Using the `createDataSource` of calling the `YamlShardingSphereDataSourceFactory` object to create `ShardingSphereDataSource` based on the configuration information in the YAML file.

Sample

The data masking YAML configurations are as follows:

```yaml
dataSources:
  unique_ds:
    dataSourceClassName: com.zaxxer.hikari.HikariDataSource
driverClassName: com.mysql.jdbc.Driver
username: root
password:

```

9.1. ShardingSphere-JDBC 75
Read the YAML configuration to create a data source according to the `createDataSource` method of `YamlShardingSphereDataSourceFactory`.

```java
YamlShardingSphereDataSourceFactory.createDataSource(getFile());
```

**Related References**

- Core Feature: Data Masking
- Developer Guide: Data Masking

**Shadow DB**

**Background**

Please refer to the following configuration in order to use the ShardingSphere shadow DB feature in `ShardingSphere-Proxy`.

**Parameters**

```yaml
rules:
  - !SHADOW
dataSources:
    shadowDataSource:
      productionDataSourceName: # production data source name
      shadowDataSourceName: # shadow data source name
tables:
  <table_name>:
    dataSourceNames: # shadow table associates shadow data source name list
    - <shadow_data_source>
    shadowAlgorithmNames: # shadow table associates shadow algorithm name list
    - <shadow_algorithm_name>
    defaultShadowAlgorithmName: # default shadow algorithm name (option)
    shadowAlgorithms:
      <shadow_algorithm_name> (+): # shadow algorithm name
type: # shadow algorithm type
props: # shadow algorithm attribute configuration
```

Please refer to [Built-in shadow algorithm list](#) for more details.
Procedure

1. Configure shadow DB rules in the YAML file, including data sources, shadow library rules, global properties and other configuration items;

2. Call the `createDataSource()` method of the `YamlShardingSphereDataSourceFactory` object to create a `ShardingSphereDataSource` based on the configuration information in the YAML file.

Sample

The YAML configuration sample of shadow DB is as follows:

```yaml
dataSources:
  ds:
    url: jdbc:mysql://127.0.0.1:3306/ds?serverTimezone=UTC&useSSL=false
    username: root
    password:
    connectionTimeoutMilliseconds: 30000
    idleTimeoutMilliseconds: 60000
    maxLifetimeMilliseconds: 1800000
    maxPoolSize: 50
    minPoolSize: 1
  shadow_ds:
    url: jdbc:mysql://127.0.0.1:3306/shadow_ds?serverTimezone=UTC&useSSL=false
    username: root
    password:
    connectionTimeoutMilliseconds: 30000
    idleTimeoutMilliseconds: 60000
    maxLifetimeMilliseconds: 1800000
    maxPoolSize: 50
    minPoolSize: 1

rules:
- !SHADOW
dataSources:
  shadowDataSource:
    productionDataSourceName: ds
    shadowDataSourceName: shadow_ds
tables:
  t_order:
    dataSourceNames:
    - shadowDataSource
    shadowAlgorithmNames:
    - user_id_insert_match_algorithm
    - sql_hint_algorithm
    shadowAlgorithms:
      user_id_insert_match_algorithm:
Related References

- Core Features of Shadow DB

SQL-parser

Background

The SQL parser YAML configuration is readable and easy to use. The YAML files allow you to separate the code from the configuration, and easily modify the configuration file as needed.

Parameters

```yaml
sqlParser:
  sqlStatementCache: # SQL statement local cache
    initialCapacity: # Initial capacity of local cache
    maximumSize: # Maximum capacity of local cache
  parseTreeCache: # Parse tree local cache
    initialCapacity: # Initial capacity of local cache
    maximumSize: # Maximum capacity of local cache
```

Procedure

1. Set local cache configuration.
2. Set parser configuration.
3. Use a parsing engine to parse SQL.
Sample

```yaml
sqlParser:
  sqlStatementCache:
    initialCapacity: 2000
    maximumSize: 65535
  parseTreeCache:
    initialCapacity: 128
    maximumSize: 1024
```

Related References

- JAVA API: SQL Parsing

SQL Translator

Background

The SQL translator YAML configuration is readable and easy to use. The YAML files allow you to separate the code from the configuration, and easily modify the configuration file as needed.

Parameters

```yaml
sqlTranslator:
  type: # SQL translator type
  useOriginalSQLWhenTranslatingFailed: # Whether use original SQL when translating failed
```

Procedure

1. Set SQL translator type.
2. Set useOriginalSQLWhenTranslatingFailed to decide whether use original SQL when translating failed.
Sample

```yaml
sqlTranslator:
  type: Jooq
  useOriginalSQLWhenTranslatingFailed: true
```

Related References

- JAVA API: SQL Translator

Mixed Rules

Background

ShardingSphere provides a variety of features, such as data sharding, read/write splitting, and data encryption. These features can be used independently or in combination. Below, you will find the parameters’ explanation and configuration samples based on YAML.

Parameters

```yaml
rules:
  - !SHARDING
    tables:
      <logic_table_name>: # Logical table name:
        actualDataNodes: # consists of logical data source name plus table name
        (refer to Inline syntax rules)
        tableStrategy: # Table shards strategy. The same as database shards strategy
        standard:
          shardingColumn: # Sharding column name
          shardingAlgorithmName: # Sharding algorithm name
        keyGenerateStrategy:
          column: # Auto-increment column name. By default, the auto-increment primary key generator is not used.
          keyGeneratorName: # Distributed sequence algorithm name
        defaultDatabaseStrategy:
          standard:
            shardingColumn: # Sharding column name
            shardingAlgorithmName: # Sharding algorithm name
        shardingAlgorithms:
          <sharding_algorithm_name>: # Sharding algorithm name
            type: INLINE
            props:
              algorithm-expression: # INLINE expression
            t_order_inline:
              type: INLINE
```

9.1. ShardingSphere-JDBC
 Samples

rules:
  - !SHARDING
tables:
    t_order:
      actualDataNodes: replica_ds_${0..1}.t_order_${0..1}
tableStrategy:
    standard:
      shardingColumn: order_id
      shardingAlgorithmName: t_order_inline
keyGenerateStrategy:
  column: order_id
  keyGeneratorName: snowflake
defaultDatabaseStrategy:
  standard:
    shardingColumn: user_id
    shardingAlgorithmName: database_inline
shardingAlgorithms:
  database_inline:
type: INLINE
props:
  algorithm-expression: replica_ds_${user_id % 2}

\( t_{\text{order-inline}}: \)
type: INLINE
props:
  algorithm-expression: \( t_{\text{order-${order_id % 2}} \)

\( t_{\text{order-item-inline}}: \)
type: INLINE
props:
  algorithm-expression: \( t_{\text{order-item-${order_id % 2}} \)

keyGenerators:
  snowflake:
    type: SNOWFLAKE
- !ENCRYPT
  encryptors:
    aes_encryptor:
      type: AES
      props:
        aes-key-value: 123456abc
    assisted_encryptor:
      type: MD5
    like_encryptor:
      type: CHAR_DIGEST_LIKE

tables:
  t_encrypt:
    columns:
      user_id:
        cipher:
          name: user_cipher
          encryptorName: aes_encryptor
      order_id:
        cipher:
          name: order_cipher
          encryptorName: aes_encryptor
Cache for Sharding Route

Background

This feature is experimental and needs to be used with the data sharding rule. The cache for sharding route will put the logical SQL, the parameter value of the shard key, and the routing result into the cache, exchange space for time, and reduce CPU usage of the routing logic.

We recommend enabling it only if the following conditions are met: - Pure OLTP scenarios. - The CPU of the machine which deployed the ShardingSphere process has reached the bottleneck. - Most of the CPUs are used by ShardingSphere routing logic. - All SQLs are optimized and each SQL execution could be routed to a single data node.

If the above conditions are not met, the execution delay of SQL may not be significantly improved, and the memory pressure will be increased.

Parameters

rules:
- !SHARDING
tables:
  shardingAlgorithms:
  # ...
  shardingCache:
    allowedMaxSqlLength: 512 # Allow cached SQL length limit
    routeCache:
      initialCapacity: 65536 # Initial capacity
      maximumSize: 262144 # Maximum capacity
      softValues: true # Whether to use soft references

Related References

- Core Feature: Data Sharding

Single Table

Background

Single rule is used to specify which single tables need to be managed by ShardingSphere, or to set the default single table data source.
Parameters

rules:
- !SINGLE
  tables:
    # MySQL style
    - ds_0.t_single # Load specified single table
    - ds_1.* # Load all single tables in the specified data source
    - "*.*" # Load all single tables
    # PostgreSQL style
    - ds_0.public.t_config
    - ds_1.public.*
    - ds_2.*.*
    - "*.*.*"
  defaultDataSource: ds_0 # The default data source is used when executing CREATE TABLE statement to create a single table. The default value is null, indicating random unicast routing.

Related References

- Single Table

Algorithm

Sharding

shardingAlgorithms:
  # algorithmName is specified by users, and its property has to be consistent with that of shardingAlgorithmName in the sharding strategy.
  <algorithmName>:
    type: xxx
    props:
      xxx: xxx
Encryption

encryptors:

# encryptorName is specified by users, and its property should be consistent with
# that of encryptorName in encryption rules.
<encryptorName>:

# type and props, please refer to the built-in encryption algorithm: https://
# shardingsphere.apache.org/document/current/en/user-manual/common-config/builtin-
# algorithm/encrypt/
  type: xxx
  props:
    xxx: xxx

Read/Write Splitting Load Balancer

loadBalancers:

# loadBalancerName is specified by users, and its property has to be consistent
# with that of loadBalancerName in read/write splitting rules.
# type and props, please refer to the built-in read/write splitting algorithm
  common-config/builtin-algorithm/load-balance/
  type: xxx
  props:
    xxx: xxx

Shadow DB

shadowAlgorithms:

# shadowAlgorithmName is specified by users, and its property has to be
# consistent with that of shadowAlgorithmNames in shadow DB rules.
<shadowAlgorithmName>:

# type and props, please refer to the built-in shadow DB algorithm: https://
# shardingsphere.apache.org/document/current/en/user-manual/common-config/builtin-
# algorithm/shadow/
  type: xxx
  props:
    xxx: xxx
High Availability

discoveryTypes:
  # discoveryTypeName is specified by users, and its property has to be consistent with that of discoveryTypeName in the database discovery rules.
  type: xxx
  props:
    xxx: xxx

Data Masking

maskAlgorithms:
  # maskAlgorithmName is specified by users, and its property should be consistent with that of maskAlgorithm in mask rules.
  <maskAlgorithmName>:
    type: xxx
    props:
      xxx: xxx

JDBC Driver

Background

ShardingSphere-JDBC provides a JDBC Driver, which can be used only through configuration changes without rewriting the code.

Parameters

Driver Class Name

org.apache.shardingsphere.driver.ShardingSphereDriver

URL Configuration

• Use jdbc:shardingsphere: as prefix
• Configuration file: xxx.yaml, keep consist format with YAML Configuration
• Configuration file loading rule:
  – absolutepath: prefix means to load the configuration file from the absolute path
  – classpath: prefix indicates that the configuration file is loaded from the classpath
Procedure

1. Import Maven Dependency

```xml
<dependency>
    <groupId>org.apache.shardingsphere</groupId>
    <artifactId>shardingsphere-jdbc-core</artifactId>
    <version>${shardingsphere.version}</version>
</dependency>
```

2. Use drive

   • Use native drivers:

```java
Class.forName("org.apache.shardingsphere.driver.ShardingSphereDriver");
String jdbcUrl = "jdbc:shardingsphere:classpath:config.yaml";
String sql = "SELECT i.* FROM t_order o JOIN t_order_item i ON o.order_id=i.order_id WHERE o.user_id=? AND o.order_id=?";
try {
    Connection conn = DriverManager.getConnection(jdbcUrl);
    PreparedStatement ps = conn.prepareStatement(sql) {
        ps.setInt(1, 10);
        ps.setInt(2, 1000);
        try (ResultSet rs = preparedStatement.executeQuery()) {
            while (rs.next()) {
                // ...
            }
        }
    }
}
```

   • Use database connection pool:

```java
String driverClassName = "org.apache.shardingsphere.driver.ShardingSphereDriver";
String jdbcUrl = "jdbc:shardingsphere:classpath:config.yaml";

// Take HikariCP as an example
HikariDataSource dataSource = new HikariDataSource();
dataSource.setDriverClassName(driverClassName);
dataSource.setJdbcUrl(jdbcUrl);

String sql = "SELECT i.* FROM t_order o JOIN t_order_item i ON o.order_id=i.order_id WHERE o.user_id=? AND o.order_id=?";
try {
    Connection conn = dataSource.getConnection();
    PreparedStatement ps = conn.prepareStatement(sql) {
        ps.setInt(1, 10);
        ps.setInt(2, 1000);
        try (ResultSet rs = preparedStatement.executeQuery()) {
            while (rs.next()) {
                // ...
            }
        }
    }
}
Sample

Load JDBC URL of config.yaml profile in classpath:

```
jdbc:shardingsphere:classpath:config.yaml
```

Load JDBC URL of config.yaml profile in absolute path

```
jdbc:shardingsphere:absolutepath:/path/to/config.yaml
```

Spring Boot

Overview

ShardingSphere provides a JDBC driver, and developers can configure ShardingSphereDriver in Spring Boot to use ShardingSphere.

Usage

Import Maven Dependency

```
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-jdbc-core</artifactId>
  <version>${shardingsphere.version}</version>
</dependency>
```

Configure Spring Boot Properties

```
# Configuring DataSource Drivers
spring.datasource.driver-class-name=org.apache.shardingsphere.driver.
ShardingSphereDriver
# Specify a YAML configuration file
spring.datasource.url=jdbc:shardingsphere:classpath:xxx.yaml
```

The YAML configuration file in ‘spring.datasource.url’ currently support in two ways, the absolute path ‘absolutepath:’ and CLASSPATH ‘classpath:’, which can be referred to org.apache.
shardingsphere.driver.jdbc.core.driver.ShardingSphereURLProvider’s implementation for details.

**Use Data Source**

Use this data source directly; or configure ShardingSphereDataSource to be used in conjunction with ORM frameworks such as JPA, Hibernate, and MyBatis.

**Handling for Spring Boot OSS 3**

Spring Boot OSS 3 has made a “big bang” upgrade to Jakarta EE and Java 17, with all complications involved.

ShardingSphere’s XA distributed transactions are not yet ready on Spring Boot OSS 3. This limitation also applies to other Jakarta EE 9+ based Web Frameworks, such as Quarkus 3, Micronaut Framework 4 and Helidon 3.

Users only need to configure as follows.

```xml
<project>
  <dependencies>
    <dependency>
      <groupId>org.apache.shardingsphere</groupId>
      <artifactId>shardingsphere-jdbc-core</artifactId>
      <version>${shardingsphere.version}</version>
    </dependency>
  </dependencies>
</project>
```

**Special handling for earlier versions of Spring Boot OSS 2**

All features of ShardingSphere are available on Spring Boot OSS 2, but earlier versions of Spring Boot OSS may require manually specifying version 2.2 for SnakeYAML. This is reflected in Maven’s pom.xml as follows.

```xml
<project>
  <dependencies>
    <dependency>
      <groupId>org.apache.shardingsphere</groupId>
      <artifactId>shardingsphere-jdbc-core</artifactId>
      <version>${shardingsphere.version}</version>
    </dependency>
    <dependency>
      <groupId>org.yaml</groupId>
      <artifactId>snakeyaml</artifactId>
      <version>2.2</version>
    </dependency>
  </dependencies>
</project>
```
If the user created the Spring Boot project from https://start.spring.io/, users can simplify configuration by following things.

```xml
<project>
  <properties>
    <snakeyaml.version>2.2</snakeyaml.version>
  </properties>

  <dependencies>
    <dependency>
      <groupId>org.apache.shardingsphere</groupId>
      <artifactId>shardingsphere-jdbc-core</artifactId>
      <version>${shardingsphere.version}</version>
    </dependency>
  </dependencies>
</project>
```

**Spring Namespace**

**Overview**

ShardingSphere provides a JDBC driver. To use ShardingSphere, developers can configure ShardingSphereDriver in Spring.

**Operation**

**Import Maven Dependency**

```xml
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-jdbc-core</artifactId>
  <version>${shardingsphere.version}</version>
</dependency>
```
Configure Spring Bean

Configuration Item Explanation

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>driverClass</td>
<td>Attribute</td>
<td>Database Driver, need to use ShardingSphereDriver</td>
</tr>
<tr>
<td>url</td>
<td>Attribute</td>
<td>YAML configuration file path</td>
</tr>
</tbody>
</table>

Example

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://www.springframework.org/schema/beans
   http://www.springframework.org/schema/beans/spring-beans.xsd">
  <bean id="shardingDataSource" class="org.springframework.jdbc.datasource.
SimpleDriverDataSource">  
    <property name="driverClass" value="org.apache.shardingsphere.driver.
ShardingSphereDriver" />
    <property name="url" value="jdbc:shardingsphere:classpath:xxx.yaml" />
  </bean>
</beans>
```

Use Data Source

Same with Spring Boot.

9.1.2 Java API

Overview

Java API is the basic configuration methods in ShardingSphere-JDBC, and other configurations will eventually be transformed into Java API configuration methods.

The Java API is the most complex and flexible configuration method, which is suitable for the scenarios requiring dynamic configuration through programming.
Usage

Import Maven Dependency

```xml
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-jdbc-core</artifactId>
  <version>${shardingsphere.version}</version>
</dependency>
```

Create DataSource

ShardingSphere-JDBC Java API consists of database name, mode configuration, data source map, rule configurations and properties.

The ShardingSphereDataSource created by ShardingSphereDataSourceFactory implements the standard JDBC DataSource interface.

```java
String databaseName = "foo_schema"; // Indicate logic database name
ModeConfiguration modeConfig = ... // Build mode configuration
Map<String, DataSource> dataSourceMap = ... // Build actual data sources
Collection<RuleConfiguration> ruleConfigs = ... // Build concentrate rule configurations
Properties props = ... // Build properties
DataSource dataSource = ShardingSphereDataSourceFactory.createDataSource(databaseName, modeConfig, dataSourceMap, ruleConfigs, props);
```

Please refer to Mode Configuration for more mode details.

Please refer to DataSource Configuration for more data source details.

Please refer to Rules Configuration for more rule details.

Use DataSource

Developer can choose to use native JDBC or ORM frameworks such as JPA, Hibernate or MyBatis through the DataSource.

Take native JDBC usage as an example:

```java
// Create ShardingSphereDataSource
DataSource dataSource = ShardingSphereDataSourceFactory.createDataSource(databaseName, modeConfig, dataSourceMap, ruleConfigs, props);

String sql = "SELECT i.* FROM t_order o JOIN t_order_item i ON o.order_id=i.order_id WHERE o.user_id=? AND o.order_id=?";
try {
    Connection conn = dataSource.getConnection();
    // Use SQL to retrieve data
}
```
PreparedStatement ps = conn.prepareStatement(sql) {
    ps.setInt(1, 10);
    ps.setInt(2, 1000);
    try (ResultSet rs = preparedStatement.executeQuery()) {
        while (rs.next()) {
            // ...
        }
    }
}
Standalone Persist Configuration

Class name: org.apache.shardingsphere.mode.repository.standalone.StandalonePersistRepositoryConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>String</td>
<td>Type of persist repository</td>
</tr>
<tr>
<td>props</td>
<td>Properties</td>
<td>Properties of persist repository</td>
</tr>
</tbody>
</table>

Cluster Persist Configuration

Class name: org.apache.shardingsphere.mode.repository.cluster.ClusterPersistRepositoryConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>String</td>
<td>Type of persist repository</td>
</tr>
<tr>
<td>namespace</td>
<td>String</td>
<td>Namespace of registry center</td>
</tr>
<tr>
<td>server-lists</td>
<td>String</td>
<td>Server lists of registry center</td>
</tr>
<tr>
<td>props</td>
<td>Properties</td>
<td>Properties of persist repository</td>
</tr>
</tbody>
</table>

Notes

1. Cluster mode deployment is recommended for production environment.
2. The ZooKeeper registry center is recommended for cluster mode deployment.
3. If there is configuration information in the ZooKeeper, please refer to the config information there.

Procedure

Introduce Maven Dependency

```java
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-jdbc-core</artifactId>
  <version>${latest.release.version}</version>
</dependency>
```

Notice: Please change `${latest.release.version}` to the actual version.
**Sample**

**Standalone Mode**

```java
ModeConfiguration modeConfig = createModeConfiguration();
Map<String, DataSource> dataSourceMap = ... // Building real data sources
Collection<RuleConfiguration> ruleConfigs = ... // Build specific rules
Properties props = ... // Build property configuration
DataSource dataSource = ShardingSphereDataSourceFactory.createDataSource(databaseName, modeConfig, dataSourceMap, ruleConfigs, props);

private ModeConfiguration createModeConfiguration() {
    return new ModeConfiguration("Standalone", new StandalonePersistRepositoryConfiguration("JDBC", new Properties()));
}
```

**Cluster Mode (Recommended)**

```java
ModeConfiguration modeConfig = createModeConfiguration();
Map<String, DataSource> dataSourceMap = ... // Building real data sources
Collection<RuleConfiguration> ruleConfigs = ... // Build specific rules
Properties props = ... // Build property configuration
DataSource dataSource = ShardingSphereDataSourceFactory.createDataSource(databaseName, modeConfig, dataSourceMap, ruleConfigs, props);

private ModeConfiguration createModeConfiguration() {
}
```

**Related References**

- Installation and Usage of ZooKeeper Registry Center
- Please refer to Builtin Persist Repository List for more details about type of repository.
**Data Source**

**Background**

ShardingSphere-JDBC supports all database JDBC drivers and connection pools. This section describes how to configure data sources through the JAVA API.

**Procedure**

1. **Import Maven dependency.**

```
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-jdbc-core</artifactId>
  <version>${latest.release.version}</version>
</dependency>
```

Notice: Please change `${latest.release.version}` to the actual version.

**Sample**

```java
ModeConfiguration modeConfig = // Build running mode
Map<String, DataSource> dataSourceMap = createDataSources();
Collection<RuleConfiguration> ruleConfigs = ... // Build specific rules
Properties props = ... // Build attribute configuration
DataSource dataSource = ShardingSphereDataSourceFactory.
  createDataSource(databaseName, modeConfig, dataSourceMap, ruleConfigs, props);

private Map<String, DataSource> createDataSources() {
  Map<String, DataSource> dataSourceMap = new HashMap<>();
  // Configure the 1st data source
  HikariDataSource dataSource1 = new HikariDataSource();
  dataSource1.setDriverClassName("com.mysql.jdbc.Driver");
  dataSource1.setJdbcUrl("jdbc:mysql://localhost:3306(ds_1"");
  dataSource1.setUsername("root");
  dataSource1.setPassword(""");
  dataSourceMap.put("ds_1", dataSource1);

  // Configure the 2nd data source
  HikariDataSource dataSource2 = new HikariDataSource();
  dataSource2.setDriverClassName("com.mysql.jdbc.Driver");
  dataSource2.setJdbcUrl("jdbc:mysql://localhost:3306(ds_2"");
  dataSource2.setUsername("root");
  dataSource2.setPassword(""");
  dataSourceMap.put("ds_2", dataSource2);
}
```

9.1. ShardingSphere-JDBC
Rules

Rules are pluggable part of Apache ShardingSphere. This chapter is a java rule configuration manual for ShardingSphere-JDBC.

Sharding

Background

The Java API rule configuration for data sharding, which allows users to create ShardingSphereDataSource objects directly by writing Java code, is flexible enough to integrate various types of business systems without relying on additional jar packages.

Parameters

Root Configuration

Class name: org.apache.shardingsphere.sharding.api.config.ShardingRuleConfiguration
Attributes:
<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>tables (+)</td>
<td>Collection&lt;ShardingTableRuleConfiguration&gt;</td>
<td>Sharding table rules</td>
<td></td>
</tr>
<tr>
<td>autoTables (+)</td>
<td>Collection&lt;ShardingAutoTableRuleConfiguration&gt;</td>
<td>Sharding auto table rules</td>
<td></td>
</tr>
<tr>
<td>bindingTableGroups (*)</td>
<td>Collection&lt;String&gt;</td>
<td>Binding table rules</td>
<td>Empty</td>
</tr>
<tr>
<td>defaultDatabaseShardingStrategy (?)</td>
<td>ShardingStrategyConfiguration</td>
<td>Default database sharding strategy</td>
<td>Not sharding</td>
</tr>
<tr>
<td>defaultTableShardingStrategy (?)</td>
<td>ShardingStrategyConfiguration</td>
<td>Default table sharding strategy</td>
<td>Not sharding</td>
</tr>
<tr>
<td>defaultKeyGeneratorStrategy (?)</td>
<td>KeyGeneratorConfiguration</td>
<td>Default key generator</td>
<td>Snowflake</td>
</tr>
<tr>
<td>defaultAuditStrategy (?)</td>
<td>ShardingAuditStrategyConfiguration</td>
<td>Default key auditor</td>
<td>DML_SHARDING_CONDITIONS</td>
</tr>
<tr>
<td>defaultShardingColumn (?)</td>
<td>String</td>
<td>Default sharding column name</td>

### Attributes

- **Name**
- **DataType**
- **Description**
- **Default Value**
Sharding Strategy Configuration

Standard Sharding Strategy Configuration

Class name: org.apache.shardingsphere.sharding.api.config.strategy.sharding.StandardShardingStrategyConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>shardingColumn</td>
<td>String</td>
<td>Sharding column name</td>
</tr>
<tr>
<td>shardingAlgorithmName</td>
<td>String</td>
<td>Sharding algorithm name</td>
</tr>
</tbody>
</table>

Complex Sharding Strategy Configuration

Class name: org.apache.shardingsphere.sharding.api.config.strategy.sharding.ComplexShardingStrategyConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>shardingColumns</td>
<td>String</td>
<td>Sharding column name, separated by commas</td>
</tr>
<tr>
<td>shardingAlgorithmName</td>
<td>String</td>
<td>Sharding algorithm name</td>
</tr>
</tbody>
</table>

Hint Sharding Strategy Configuration

Class name: org.apache.shardingsphere.sharding.api.config.strategy.sharding.HintShardingStrategyConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>shardingAlgorithmName</td>
<td>String</td>
<td>Sharding algorithm name</td>
</tr>
</tbody>
</table>

None Sharding Strategy Configuration

Class name: org.apache.shardingsphere.sharding.api.config.strategy.sharding.NoneShardingStrategyConfiguration

Attributes: None

Please refer to Built-in Sharding Algorithm List for more details about type of algorithm.
Distributed Key Strategy Configuration

Class name: org.apache.shardingsphere.sharding.api.config.strategy.keygen.KeyGenerateStrategyConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>String</td>
<td>Column name of key generate</td>
</tr>
<tr>
<td>keyGeneratorName</td>
<td>String</td>
<td>key generate algorithm name</td>
</tr>
</tbody>
</table>

Please refer to [Built-in Key Generate Algorithm List](#) for more details about type of algorithm.

Sharding audit Strategy Configuration

Class name: org.apache.shardingsphere.sharding.api.config.strategy.audit.ShardingAuditStrategyConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auditorNames</td>
<td>Collection&lt;String&gt;</td>
<td>Sharding audit algorithm name</td>
</tr>
<tr>
<td>allowHintDisable</td>
<td>Boolean</td>
<td>Enable or disable sharding audit hint</td>
</tr>
</tbody>
</table>

Please refer to [Built-in Sharding Audit Algorithm List](#) for more details about type of algorithm.

Procedure

1. Create an authentic data source mapping relationship, with key as the logical name of the data source and value as the DataSource object.

2. Create the sharding rule object ShardingRuleConfiguration, and initialize the sharding table objects—ShardingTableRuleConfiguration, the set of bound tables, the set of broadcast tables, and parameters like library sharding strategy and the database sharding strategy, on which the data sharding depends.

3. Using the ShardingSphereDataSource method of calling the ShardingSphereDataSourceFactory subject to create the ShardingSphereDataSource.

Sample

```java
public final class ShardingDatabasesAndTablesConfigurationPrecise {

    @Override
    public DataSource getDataSource() throws SQLException {
        return ShardingSphereDataSourceFactory.
            createDataSource(createDataSourceMap(), Arrays.
           .asList(createShardingRuleConfiguration(), createBroadcastRuleConfiguration())), new
```
private ShardingRuleConfiguration createShardingRuleConfiguration() {
    ShardingRuleConfiguration result = new ShardingRuleConfiguration();
    result.getTables().add(getOrderTableRuleConfiguration());
    result.getTables().add(getOrderItemTableRuleConfiguration());
    result.getBindingTableGroups().add(new
    ShardingTableReferenceRuleConfiguration("foo", "t_order, t_order_item");
    result.setDefaultDatabaseShardingStrategy(
    new StandardShardingStrategyConfiguration("user_id", "inline"));
    result.setDefaultTableShardingStrategy(
    new StandardShardingStrategyConfiguration("order_id", "standard_test_tbl"));
    Properties props = new Properties();
    props.setProperty("algorithm-expression", "demo_ds_${user_id % 2}";
    result.getShardingAlgorithms().put("inline", new AlgorithmConfiguration("
    INLINE", props));
    result.getShardingAlgorithms().put("standard_test_tbl", new
    AlgorithmConfiguration("STANDARD_TEST_TBL", new Properties()));
    result.getKeyGenerators().put("snowflake", new AlgorithmConfiguration("
    SNOWFLAKE", new Properties()));
    result.getAuditors().put("sharding_key_required_auditor", new
    AlgorithmConfiguration("DML_SHARDING_CONDITIONS", new Properties()));
    return result;
}

private ShardingTableRuleConfiguration getOrderTableRuleConfiguration() {
    ShardingTableRuleConfiguration result = new ShardingTableRuleConfiguration("
    t_order", "demo_ds_0..1.t_order_${[0, 1]}";
    result.setKeyGenerateStrategy(new KeyGenerateStrategyConfiguration("order_-
    id", "snowflake"));
    result.setAuditStrategy(new ShardingAuditStrategyConfiguration(Collections.
    singleton("sharding_key_required_auditor"), true));
    return result;
}

private ShardingTableRuleConfiguration getOrderItemTableRuleConfiguration() {
    ShardingTableRuleConfiguration result = new ShardingTableRuleConfiguration("
    t_order_item", "demo_ds_0..1.t_order_item_${[0, 1]}";
    result.setKeyGenerateStrategy(new KeyGenerateStrategyConfiguration("order_-
    item_id", "snowflake"));
    return result;
}

private Map<String, DataSource> createDataSourceMap() {
    Map<String, DataSource> result = new HashMap<>();
    result.put("demo_ds_0", DataSourceUtil.createDataSource("demo_ds_0"));
    result.put("demo_ds_1", DataSourceUtil.createDataSource("demo_ds_1"));

9.1. ShardingSphere-JDBC
public final class ShardingDatabasesAndTablesConfigurationPrecise {

    @Override
    public DataSource getDataSource() throws SQLException {
        return ShardingSphereDataSourceFactory.createDataSource(createDataSourceMap(), Arrays.asList(createBroadcastRuleConfiguration()), new Properties());
    }
}

Broadcast Table

Background

The Java API rule configuration for broadcast, which allows users to create ShardingSphereDataSource objects directly by writing Java code, is flexible enough to integrate various types of business systems without relying on additional jar packages.

Parameters

Class: org.apache.shardingsphere.broadcast.api.config.BroadcastRuleConfiguration

Attributes:

<table>
<thead>
<tr>
<th>name</th>
<th>DataType</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>tables (+)</td>
<td>Collection&lt;String&gt;</td>
<td>Broadcast table rules</td>
<td></td>
</tr>
</tbody>
</table>

Sample

The following is an example of the broadcast table Java API configuration:

```java
public final class ShardingDatabasesAndTablesConfigurationPrecise {

    @Override
    public DataSource getDataSource() throws SQLException {
        return ShardingSphereDataSourceFactory.createDataSource(createDataSourceMap(), Arrays.asList(createBroadcastRuleConfiguration()), new Properties());
    }
}
```
```java
private Map<String, DataSource> createDataSourceMap() {
    Map<String, DataSource> result = new HashMap<>();
    result.put("demo_ds_0", DataSourceUtil.createDataSource("demo_ds_0"));
    result.put("demo_ds_1", DataSourceUtil.createDataSource("demo_ds_1"));
    return result;
}

private BroadcastRuleConfiguration createBroadcastRuleConfiguration() {
    return new BroadcastRuleConfiguration(Collections.singletonList("t_address"));
}
```

**Readwrite-splitting**

**Background**

The read/write splitting configured in Java API form can be easily applied to various scenarios without relying on additional jar packages. Users only need to construct the read/write splitting data source through java code to be able to use the read/write splitting function.

**Parameters Explained**

**Entry**

Class name: org.apache.shardingsphere.readwritesplitting.api.ReadwriteSplittingRuleConfiguration

Configurable Properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataSources (+)</td>
<td>Collection&lt;ReadwriteSplittingDataSourceRuleConfig&gt;</td>
<td>Data sources of write and reads</td>
</tr>
<tr>
<td>loadBalancers (*)</td>
<td>Map&lt;String, AlgorithmConfiguration&gt;</td>
<td>Load balance algorithm name and configurations of replica data sources</td>
</tr>
</tbody>
</table>
Primary-secondary Data Source Configuration

Class name: org.apache.shardingsphere.readwritesplitting.api.rule.ReadwriteSplittingDataSourceRuleConfiguration

Configurable Properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
<th>Default Value*</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Readwrite-splitting data source name</td>
<td>*</td>
</tr>
<tr>
<td>write DataSource-Name</td>
<td>String</td>
<td>Write data source name</td>
<td>*</td>
</tr>
<tr>
<td>read DataSource-Nomes</td>
<td>List&lt;String&gt;</td>
<td>Read data sources list</td>
<td>*</td>
</tr>
<tr>
<td>transactionalReadQueryStrategy (?)</td>
<td>String</td>
<td>Routing strategy for read query within a transaction, values include: PRIMARY (to primary), FIXED (to fixed data source), DYNAMIC (to any data source)</td>
<td>DYNAMIC</td>
</tr>
<tr>
<td>loadBalancerName (?)</td>
<td>String</td>
<td>Load balance algorithm name of replica sources</td>
<td>Round robin load balance algorithm</td>
</tr>
</tbody>
</table>

Please refer to Built-in Load Balance Algorithm List for details on algorithm types.

Operating Procedures

1. Add read-write splitting data source
2. Set load balancing algorithms
3. Use read-write splitting data source

Configuration Examples

```java
public DataSource getDataSource() throws SQLException {
    ReadwriteSplittingDataSourceRuleConfiguration dataSourceConfig = new ReadwriteSplittingDataSourceRuleConfiguration(
        "demo_read_query_ds", "demo_write_ds", Arrays.asList("demo_read_ds_0", "demo_read_ds_1"), "demo_weight_lb");
    Properties algorithmProps = new Properties();
    ```
algorithmProps.setProperty("demo_read_ds_0", "2");
algorithmProps.setProperty("demo_read_ds_1", "1");
Map<String, AlgorithmConfiguration> algorithmConfigMap = new HashMap<>(1);
algorithmConfigMap.put("demo_weight_lb", new AlgorithmConfiguration("WEIGHT ", algorithmProps));
ReadWriteSplittingRuleConfiguration ruleConfig = new ReadWriteSplittingRuleConfiguration(Collections.singleton(dataSourceConfig),
algorithmConfigMap);
Properties props = new Properties();
props.setProperty("sql-show", Boolean.TRUE.toString());
return ShardingSphereDataSourceFactory.
createDataSource(createDataSourceMap(), Collections.singleton(ruleConfig), props);
}

private Map<String, DataSource> createDataSourceMap() {
    Map<String, DataSource> result = new HashMap<>(3, 1);
    result.put("demo_write_ds", DataSourceUtil.createDataSource("demo_write_ds "));
    result.put("demo_read_ds_0", DataSourceUtil.createDataSource("demo_read_ds_ 
0");
    result.put("demo_read_ds_1", DataSourceUtil.createDataSource("demo_read_ds_ 
1");
    return result;
}

Distributed Transaction

Root Configuration

org.apache.shardingsphere.transaction.config.TransactionRuleConfiguration

Attributes:

<table>
<thead>
<tr>
<th>name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>defaultType</td>
<td>String</td>
<td>Default transaction type</td>
</tr>
<tr>
<td>providerType</td>
<td>String</td>
<td>Transaction provider type</td>
</tr>
<tr>
<td>props</td>
<td>Properties</td>
<td>Transaction properties</td>
</tr>
</tbody>
</table>
Encryption

Background

The data encryption Java API rule configuration allows users to directly create ShardingSphereDataSource objects by writing java code. The Java API configuration method is very flexible and can integrate various types of business systems without relying on additional jar packages.

Parameters

Root Configuration

Class name: org.apache.shardingsphere.encrypt.api.config.EncryptRuleConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>tables (+)</td>
<td>Collection&lt;EncryptTableRuleConfiguration&gt;</td>
<td>Encrypt table rule configurations</td>
<td></td>
</tr>
<tr>
<td>encryptors (+)</td>
<td>Map&lt;String, Algorithm Configuration&gt;</td>
<td>Encrypt algorithm name and configurations</td>
<td></td>
</tr>
</tbody>
</table>

Encrypt Table Rule Configuration

Class name: org.apache.shardingsphere.encrypt.api.config.rule.EncryptTableRuleConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Table name</td>
</tr>
<tr>
<td>columns (+)</td>
<td>Collection&lt;EncryptColumnRuleConfiguration&gt;</td>
<td>Encrypt column rule configurations</td>
</tr>
</tbody>
</table>

Encrypt Column Rule Configuration

Class name: org.apache.shardingsphere.encrypt.api.config.rule.EncryptColumnRuleConfiguration

Attributes:
<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Logic column name</td>
</tr>
<tr>
<td>cipher</td>
<td>EncryptColumnItemRuleConfig</td>
<td>Cipher column config</td>
</tr>
<tr>
<td>assistedQuery (?)</td>
<td>EncryptColumnItemRuleConfig</td>
<td>Assisted query column config</td>
</tr>
<tr>
<td>likeQuery (?)</td>
<td>EncryptColumnItemRuleConfig</td>
<td>Like query column config</td>
</tr>
</tbody>
</table>

**Encrypt Column Item Rule Configuration**

Class name: org.apache.shardingsphere.encrypt.api.config.rule.EncryptColumnItemRuleConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>encrypt column item name</td>
</tr>
<tr>
<td>encryptorName</td>
<td>String</td>
<td>encryptor name</td>
</tr>
</tbody>
</table>

**Encrypt Algorithm Configuration**

Class name: org.apache.shardingsphere.infra.config.algorithm.AlgorithmConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Encrypt algorithm name</td>
</tr>
<tr>
<td>type</td>
<td>String</td>
<td>Encrypt algorithm type</td>
</tr>
<tr>
<td>properties</td>
<td>Properties</td>
<td>Encrypt algorithm properties</td>
</tr>
</tbody>
</table>

Please refer to [Built-in Encrypt Algorithm List](#) for more details about type of algorithm.

**Procedure**

1. Create a real data source mapping relationship, where key is the logical name of the data source and value is the datasource object.

2. Create the encryption rule object EncryptRuleConfiguration, and initialize the encryption table object EncryptTableRuleConfiguration, encryption algorithm and other parameters in the object.

3. Call `createDataSource` of `ShardingSphereDataSourceFactory` to create `ShardingSphereDataSource`.

---

9.1. ShardingSphere-JDBC
public final class EncryptDatabasesConfiguration {

    public DataSource getDataSource() throws SQLException {
        Properties props = new Properties();
        props.setProperty("aes-key-value", "123456");
        EncryptColumnRuleConfiguration columnConfigAes = new EncryptColumnRuleConfiguration("username", new EncryptColumnItemRuleConfiguration("username", "name_encryptor"));
        EncryptColumnRuleConfiguration columnConfigTest = new EncryptColumnRuleConfiguration("pwd", new EncryptColumnItemRuleConfiguration("pwd", "pwd_encryptor"));
        columnConfigTest.setAssistedQuery(new EncryptColumnItemRuleConfiguration("assisted_query_pwd", "pwd_encryptor"));
        columnConfigTest.setLikeQuery(new EncryptColumnItemRuleConfiguration("like_pwd", "like_encryptor"));
        EncryptTableRuleConfiguration encryptTableRuleConfig = new EncryptTableRuleConfiguration("t_user", Arrays.asList(columnConfigAes, columnConfigTest));
        Map<String, AlgorithmConfiguration> encryptAlgorithmConfigs = new HashMap<>();
        encryptAlgorithmConfigs.put("name_encryptor", new AlgorithmConfiguration( "AES", props));
        encryptAlgorithmConfigs.put("pwd_encryptor", new AlgorithmConfiguration( "assistedTest", props));
        encryptAlgorithmConfigs.put("like_encryptor", new AlgorithmConfiguration( "CHAR_DIGEST_LIKE", new Properties()));
        EncryptRuleConfiguration encryptRuleConfig = new EncryptRuleConfiguration(Collections.singleton(encryptTableRuleConfig), encryptAlgorithmConfigs);
        return ShardingSphereDataSourceFactory.createDataSource(DataSourceUtil.createDataSource("demo_ds"), Collections.singleton(encryptRuleConfig), props);
    }
}

Data Masking

Background

The data masking Java API rule configuration allows users to directly create ShardingSphereDataSource objects by writing java code. The Java API configuration method is very flexible and can integrate various types of business systems without relying on additional jar packages.

Parameters

Root Configuration

Class name: org.apache.shardingsphere.mask.api.config.MaskRuleConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>tables (+)</td>
<td>Collection&lt;MaskTableRuleConfiguration&gt;</td>
<td>Mask table rule configurations</td>
<td></td>
</tr>
<tr>
<td>maskAlgorithms (+)</td>
<td>Map&lt;String, AlgorithmConfiguration&gt;</td>
<td>Mask algorithm name and configurations</td>
<td></td>
</tr>
</tbody>
</table>

Mask Table Rule Configuration

Class name: org.apache.shardingsphere.mask.api.config.rule.MaskTableRuleConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Table name</td>
</tr>
<tr>
<td>columns (+)</td>
<td>Collection&lt;MaskColumnRuleConfiguration&gt;</td>
<td>Mask column rule configurations</td>
</tr>
</tbody>
</table>

Mask Column Rule Configuration

Class name: org.apache.shardingsphere.mask.api.config.rule.MaskColumnRuleConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logicColumn</td>
<td>String</td>
<td>Logic column name</td>
</tr>
<tr>
<td>maskAlgorithm</td>
<td>String</td>
<td>Mask algorithm name</td>
</tr>
</tbody>
</table>
Mask Algorithm Configuration

Class name: org.apache.shardingsphere.infra.config.algorithm.AlgorithmConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Mask algorithm name</td>
</tr>
<tr>
<td>type</td>
<td>String</td>
<td>Mask algorithm type</td>
</tr>
<tr>
<td>properties</td>
<td>Properties</td>
<td>Mask algorithm properties</td>
</tr>
</tbody>
</table>

Please refer to Built-in Data Masking Algorithm List for more details about type of algorithm.

Procedure

1. Create a real data source mapping relationship, where key is the logical name of the data source and value is the datasource object.
2. Create the data masking rule object MaskRuleConfiguration, and initialize the mask table object MaskTableRuleConfiguration, mask algorithm and other parameters in the object.
3. Call createDataSource of ShardingSphereDataSourceFactory to create ShardingSphereDataSource.

Sample

```java
import java.util.Collections;
import java.util.LinkedHashMap;
import java.util.Properties;

public final class MaskDatabasesConfiguration {
    @Override
    public DataSource getDataSource() throws SQLException {
        MaskColumnRuleConfiguration passwordColumn = new MaskColumnRuleConfiguration("password", "md5_mask");
        MaskColumnRuleConfiguration emailColumn = new MaskColumnRuleConfiguration("email", "mask_before_special_chars_mask");
        MaskColumnRuleConfiguration telephoneColumn = new MaskColumnRuleConfiguration("telephone", "keep_first_n_last_m_mask");
        MaskTableRuleConfiguration maskTableRuleConfig = new MaskTableRuleConfiguration("t_user", Arrays.asList(passwordColumn, emailColumn, telephoneColumn));
        Map<String, AlgorithmConfiguration> maskAlgorithmConfigs = new LinkedHashMap<>(3, 1);
        maskAlgorithmConfigs.put("md5_mask", new AlgorithmConfiguration("MD5", new Properties()));
        // More configurations...
    }
}
```
Properties beforeSpecialCharsProps = new Properties();
   beforeSpecialCharsProps.put("special-chars", "+");
   beforeSpecialCharsProps.put("replace-char", "+");
   maskAlgorithmConfigs.put("mask_before_special_chars_mask", new AlgorithmConfiguration("MASK_BEFORE_SPECIAL_CHARS", beforeSpecialCharsProps));

Properties keepFirstNLastMProps = new Properties();
   keepFirstNLastMProps.put("first-n", "3");
   keepFirstNLastMProps.put("last-m", "4");
   keepFirstNLastMProps.put("replace-char", "+");
   maskAlgorithmConfigs.put("keep_first_n_last_m_mask", new AlgorithmConfiguration("KEEP_FIRST_N_LAST_M", keepFirstNLastMProps));

MaskRuleConfiguration maskRuleConfig = new MaskRuleConfiguration(Collections.singleton(maskTableRuleConfig), maskAlgorithmConfigs);
   return ShardingSphereDataSourceFactory.createDataSource(DataSourceUtil.createDataSource("demo_ds"), Collections.singleton(maskRuleConfig), new Properties());
}

Shadow DB

Background

In the distributed application architecture based on microservices, businesses require multiple services to be completed through a series of services and middleware, so the stress test of a single service can no longer meet the needs of real scenarios. If we reconstruct a stress test environment similar to the production environment, it is too expensive and often fails to simulate the complexity and traffic of the online environment. For this reason, the industry often chooses the full link stress test, which is performed in the production environment, so that the test results can accurately reflect the true capacity and performance of the system.
Parameters

Root Configuration

Class name: org.apache.shardingsphere.shadow.api.config.ShadowRuleConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataSources</td>
<td>Map&lt;String, ShadowDataSourceConfig&gt;</td>
<td>shadow data source mapping name and configuration</td>

<tr>
<td>tables</td>
<td>Map&lt;String, ShadowTableConfiguration&gt;</td>
<td>shadow table name and configuration</td>
</tr>
<tr>
<td>shadowAlgorithms</td>
<td>Map&lt;String, AlgorithmConfiguration&gt;</td>
<td>shadow algorithm name and configuration</td>
</tr>
<tr>
<td>defaultShadowAlgorithmName</td>
<td>String</td>
<td>default shadow algorithm name</td>
</tr>
</tbody>
</table>

Shadow DataSource Configuration

Class name: org.apache.shardingsphere.shadow.api.config.datasource.ShadowDataSourceConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>productionDataSourceName</td>
<td>String</td>
<td>Production data source name</td>
</tr>
<tr>
<td>shadowDataSourceName</td>
<td>String</td>
<td>Shadow data source name</td>
</tr>
</tbody>
</table>

Shadow Table Configuration

Class name: org.apache.shardingsphere.shadow.api.config.table.ShadowTableConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataSourceNames</td>
<td>Collection&lt;String&gt;</td>
<td>shadow table associates shadow data source mapping name list</td>
</tr>
<tr>
<td>shadowAlgorithmNames</td>
<td>Collection&lt;String&gt;</td>
<td>shadow table associates shadow algorithm name list</td>
</tr>
</tbody>
</table>
Shadow Algorithm Configuration

Class name: org.apache.shardingsphere.infra.config.algorithm.AlgorithmConfiguration

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>String</td>
<td>shadow algorithm type</td>
</tr>
<tr>
<td>props</td>
<td>Properties</td>
<td>shadow algorithm configuration</td>
</tr>
</tbody>
</table>

Please refer to Built-in Shadow Algorithm List.

Procedure

1. Create production and shadow data source.
2. Configure shadow rule.
   - Configure shadow data source
   - Configure shadow table
   - Configure shadow algorithm

Sample

```java
public final class ShadowConfiguration {

    @Override
    public DataSource getDataSource() throws SQLException {
        Map<String, DataSource> dataSourceMap = createDataSourceMap();
        return ShardingSphereDataSourceFactory.createDataSource(dataSourceMap,
                                                                  createRuleConfigurations(),
                                                                  createShardingSphereProps());
    }

    private Map<String, DataSource> createDataSourceMap() {
        Map<String, DataSource> result = new LinkedHashMap<>();
        result.put("ds", DataSourceUtil.createDataSource("demo_ds"));
        result.put("ds_shadow", DataSourceUtil.createDataSource("shadow_demo_ds"));
        return result;
    }

    private Collection<RuleConfiguration> createRuleConfigurations() {
        Collection<RuleConfiguration> result = new LinkedList<>();
        ShardingRuleConfiguration shadowRule = new ShardingRuleConfiguration();
        shadowRule.setDataSources(createShadowDataSources());
        shadowRule.setTables(createShadowTables());
        shadowRule.setShadowAlgorithms(createShadowAlgorithmConfigurations());
        result.add(shadowRule);
        return result;
    }

    private Connection<RuleConfiguration> createShadowDataSources() {
        return new ShardingRuleConfiguration();
    }
}
```
private Map<String, ShadowDataSourceConfiguration> createShadowDataSources() {
    Map<String, ShadowDataSourceConfiguration> result = new LinkedHashMap<>();
    result.put("shadow-data-source", new ShadowDataSourceConfiguration("ds", "ds_shadow"));
    return result;
}

private Map<String, ShadowTableConfiguration> createShadowTables() {
    Map<String, ShadowTableConfiguration> result = new LinkedHashMap<>();
    result.put("t_user", new ShadowTableConfiguration(Collections.singletonList("shadow-data-source"), createShadowAlgorithmNames()));
    return result;
}

private Collection<String> createShadowAlgorithmNames() {
    Collection<String> result = new LinkedList<>();
    result.add("user-id-insert-match-algorithm");
    result.add("simple-hint-algorithm");
    return result;
}

private Map<String, AlgorithmConfiguration> createShadowAlgorithmConfigurations() {
    Map<String, AlgorithmConfiguration> result = new LinkedHashMap<>();
    Properties userIdInsertProps = new Properties();
    userIdInsertProps.setProperty("operation", "insert");
    userIdInsertProps.setProperty("column", "user_type");
    userIdInsertProps.setProperty("value", "1");
    result.put("user-id-insert-match-algorithm", new AlgorithmConfiguration("VALUE_MATCH", userIdInsertProps));
    return result;
}

Features Description of Shadow DB

SQL Parser

Background

SQL is the standard language for users to communicate with databases. The SQL parsing engine is responsible for parsing the SQL string into an abstract syntax tree for Apache ShardingSphere to understand and implement its incremental function. Currently, MySQL, PostgreSQL, SQLServer, Oracle, openGauss and SQL dialects conforming to SQL92 specifications are supported. Due to the complexity of SQL syntax, there are still a few unsupported SQLs. By using SQL parsing in the form of Java API, you can easily integrate into various systems and flexibly customize user requirements.

Parameters

Class: `org.apache.shardingsphere.parser.config.SQLParserRuleConfiguration`

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parseTreeCache (?)</td>
<td>CacheOption</td>
<td>Parse syntax tree local cache configuration</td>
</tr>
<tr>
<td>sqlStatementCache (?)</td>
<td>CacheOption</td>
<td>Sql statement local cache configuration</td>
</tr>
</tbody>
</table>

Cache option Configuration

Class: `org.apache.shardingsphere.sql.parser.api.CacheOption`

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>initialCapacity</td>
<td>int</td>
<td>Initial capacity of local cache</td>
</tr>
<tr>
<td>maximumSize (?)</td>
<td>long</td>
<td>Maximum capacity of local cache</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>initialCapacity</td>
<td>int</td>
<td>Initial capacity of local cache</td>
</tr>
<tr>
<td>maximumSize (?)</td>
<td>long</td>
<td>Maximum capacity of local cache</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>initialCapacity</td>
<td>int</td>
<td>Initial capacity of local cache</td>
</tr>
<tr>
<td>maximumSize (?)</td>
<td>long</td>
<td>Maximum capacity of local cache</td>
</tr>
</tbody>
</table>

The default value of local cache for parsing syntax tree is 1024, and the default value of sql statement cache is 65535.

116
Procedure

1. Set local cache configuration.
2. Set resolution configuration.
3. Use the parsing engine to parse SQL.

Sample

```java
CacheOption cacheOption = new CacheOption(128, 1024L);
SQLParserEngine parserEngine = new SQLParserEngine("MySQL", cacheOption);
ParseASTNode parseASTNode = parserEngine.parse("SELECT t.id, t.name, t.age FROM table1 AS t ORDER BY t.id DESC;", false);

SQLStatementVisitorEngine visitorEngine = new SQLStatementVisitorEngine("MySQL");
MySQLStatement sqlStatement = visitorEngine.visit(parseASTNode);
System.out.println(sqlStatement.toString());
```

SQL Translator

Background

By using SQL translator in the form of Java API, you can easily integrate into various systems and flexibly customize user requirements.

Parameters

Class: org.apache.shardingsphere.sqltranslator.api.config.SQLTranslatorRuleConfiguration

Attributes:

<table>
<thead>
<tr>
<th>name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>String</td>
<td>SQL translator type</td>
</tr>
<tr>
<td>useOriginalFailed (?)</td>
<td>boolean</td>
<td>Whether use original SQL when translating failed</td>
</tr>
</tbody>
</table>
Procedure

1. Set SQL translator type.

2. Set `useOriginalSQLWhenTranslatingFailed` to decide whether use original SQL when translating failed.

Sample

```java
SQLTranslatorRuleConfiguration ruleConfig = new SQLTranslatorRuleConfiguration("Jooq", new Properties(), false);
String translatedSQL = new SQLTranslatorRule(ruleConfig).translate();
```

- YAML Configuration: SQL Translator

Mixed Rules

Background

ShardingSphere provides a variety of features, such as data sharding, read/write splitting, high availability, and data encryption. These features can be used independently or in combination. Below, you will find the configuration samples based on JAVA API.

Samples

```java
// Sharding configuration
private ShardingRuleConfiguration createShardingRuleConfiguration() {
    ShardingRuleConfiguration result = new ShardingRuleConfiguration();
    result.getTables().add(getOrderTableRuleConfiguration());
    result.setDefaultDatabaseShardingStrategy(new StandardShardingStrategyConfiguration("user_id", "inline"));
    result.setDefaultTableShardingStrategy(new StandardShardingStrategyConfiguration("order_id", "standard_test_tbl"));
    Properties props = new Properties();
    props.setProperty("algorithm-expression", "demo_ds_${user_id % 2}");
    result.getShardingAlgorithms().put("inline", new AlgorithmConfiguration("INLINE", props));
    result.getShardingAlgorithms().put("standard_test_tbl", new AlgorithmConfiguration("STANDARD_TEST_TBL", new Properties()));
    result.getKeyGenerators().put("snowflake", new AlgorithmConfiguration("SNOWFLAKE", new Properties()));
    return result;
```
private ShardingTableRuleConfiguration getOrderTableRuleConfiguration() {
    ShardingTableRuleConfiguration result = new ShardingTableRuleConfiguration("t_order", "demo_ds_${0..1}.t_order_${[0, 1]}");
    result.setKeyGenerateStrategy(new KeyGenerateStrategyConfiguration("order_id", "snowflake"));
    return result;
}

// Read/write splitting configuration
private static ReadWriteSplittingRuleConfiguration createReadWriteSplittingConfiguration() {
    ReadWriteSplittingDataSourceRuleConfiguration dataSourceConfiguration1 = new ReadWriteSplittingDataSourceRuleConfiguration("replica_ds_0", Arrays.asList("readwrite_ds_0", true), "");
    ReadWriteSplittingDataSourceRuleConfiguration dataSourceConfiguration2 = new ReadWriteSplittingDataSourceRuleConfiguration("replica_ds_1", Arrays.asList("readwrite_ds_1", true), "");
    Collection<ReadWriteSplittingDataSourceRuleConfiguration> dataSources = new LinkedList<>();
    dataSources.add(dataSourceRuleConfiguration1);
    dataSources.add(dataSourceRuleConfiguration2);
    return new ReadWriteSplittingRuleConfiguration(dataSources, Collections.emptyMap());
}

// Data encryption configuration
private static EncryptRuleConfiguration createEncryptRuleConfiguration() {
    Properties props = new Properties();
    props.setProperty("aes-key-value", "123456");
    EncryptColumnRuleConfiguration columnConfigAes = new EncryptColumnRuleConfiguration("username", new EncryptColumnItemRuleConfiguration("username", "name_encryptor"));
    EncryptColumnRuleConfiguration columnConfigTest = new EncryptColumnRuleConfiguration("pwd", new EncryptColumnItemRuleConfiguration("pwd", "pwd_encryptor"));
    columnConfigTest.setAssistedQuery(new EncryptColumnItemRuleConfiguration("assisted_query_pwd", "pwd_encryptor"));
    columnConfigTest.setLikeQuery(new EncryptColumnItemRuleConfiguration("like_pwd", "like_encryptor"));
    EncryptTableRuleConfiguration encryptTableRuleConfig = new EncryptTableRuleConfiguration("t_user", Arrays.asList(columnConfigAes, columnConfigTest));
    Map<String, AlgorithmConfiguration> encryptAlgorithmConfigs = new HashMap<>();
    encryptAlgorithmConfigs.put("name_encryptor", new AlgorithmConfiguration("AES", props));
    encryptAlgorithmConfigs.put("pwd_encryptor", new AlgorithmConfiguration(9.1. ShardingSphere-JDBC 119}
"assistedTest", props));
    encryptAlgorithmConfigs.put("like_encryptor", new AlgorithmConfiguration("CHAR_DIGEST_LIKE", new Properties()));
    return new EncryptRuleConfiguration(Collections.singleton(encryptTableRuleConfig), encryptAlgorithmConfigs);
}

Cache for Sharding Route

Background

This feature is experimental and needs to be used with the data sharding rule. The cache for sharding route will put the logical SQL, the parameter value of the shard key, and the routing result into the cache, exchange space for time, and reduce CPU usage of the routing logic.

We recommend enabling it only if the following conditions are met: - Pure OLTP scenarios. - The CPU of the machine which deployed the ShardingSphere process has reached the bottleneck. - Most of the CPUs are used by ShardingSphere routing logic. - All SQLs are optimized and each SQL execution could be routed to a single data node.

If the above conditions are not met, the execution delay of SQL may not be significantly improved, and the memory pressure will be increased.

Parameters

Class: org.apache.shardingsphere.sharding.api.config.cache.ShardingCacheConfiguration

Attributes:

<table>
<thead>
<tr>
<th>name</th>
<th>DataType</th>
<th>Description</th>
<th>DefaultValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>allowdMaxSqlLength</td>
<td>int</td>
<td>允许缓存的 SQL 长度限制</td>
<td>.</td>
</tr>
</tbody>
</table>

Class: org.apache.shardingsphere.sharding.api.config.cache.ShardingCacheOptionsConfiguration

Attributes:
### Apache ShardingSphere document

<table>
<thead>
<tr>
<th>name</th>
<th>DataType</th>
<th>Description</th>
<th>DefaultValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>softValues</td>
<td>boolean</td>
<td>是否软引用缓存值</td>
<td>.</td>
</tr>
<tr>
<td>initialCapacity</td>
<td>int</td>
<td>缓存初始容量</td>
<td>.</td>
</tr>
<tr>
<td>maximumSize</td>
<td>int</td>
<td>缓存最大容量</td>
<td>.</td>
</tr>
</tbody>
</table>

**Sample**

```java
public final class ShardingDatabasesAndTablesConfigurationPrecise {

    @Override
    public DataSource getDataSource() throws SQLException {
        return ShardingSphereDataSourceFactory.createDataSource(createDataSourceMap(), Arrays.asList(createShardingRuleConfiguration(), createBroadcastRuleConfiguration()), new Properties());
    }

    private ShardingRuleConfiguration createShardingRuleConfiguration() {
        ShardingRuleConfiguration result = new ShardingRuleConfiguration();
        result.getTables().add(getOrderTableRuleConfiguration());
        result.getTables().add(getOrderItemTableRuleConfiguration());
        // ...
        result.setShardingCache(new ShardingCacheConfiguration(512, new ShardingCacheConfiguration.RouteCacheConfiguration(65536, 262144, true)));
        return result;
    }

    private ShardingTableRuleConfiguration getOrderTableRuleConfiguration() {
        ShardingTableRuleConfiguration result = new ShardingTableRuleConfiguration("t_order", "demo_ds${0..1}.t_order${[0, 1]});
        result.setKeyGenerateStrategy(new KeyGenerateStrategyConfiguration("order_id", "snowflake"));
        result.setAuditStrategy(new ShardingAuditStrategyConfiguration(Collections.singleton("sharding_key_required_auditor"), true));
        return result;
    }

    private ShardingTableRuleConfiguration getOrderItemTableRuleConfiguration() {
        ShardingTableRuleConfiguration result = new ShardingTableRuleConfiguration("t_order_item", "demo_ds${0..1}.t_order_item${[0, 1]});
        result.setKeyGenerateStrategy(new KeyGenerateStrategyConfiguration("order_item_id", "snowflake"));
    }
}
```

9.1. ShardingSphere-JDBC
private Map<String, DataSource> createDataSourceMap() {
    Map<String, DataSource> result = new HashMap<>();
    result.put("demo_ds_0", DataSourceUtil.createDataSource("demo_ds_0"));
    result.put("demo_ds_1", DataSourceUtil.createDataSource("demo_ds_1"));
    return result;
}

private BroadcastRuleConfiguration createBroadcastRuleConfiguration() {
    return new BroadcastRuleConfiguration(Collections.singletonList("t_address"));
}
Procedure

1. Initialize SingleRuleConfiguration;
2. Add a single table to be loaded and configure the default data source.

Sample

```java
SingleRuleConfiguration ruleConfig = new SingleRuleConfiguration();
ShardingSphereDataSourceFactory.createDataSource(createDataSourceMap(), Arrays.asList(ruleConfig), new Properties());
```

Related References

- Single Table

Algorithm

Sharding

```java
ShardingRuleConfiguration ruleConfiguration = new ShardingRuleConfiguration();
// algorithmName is specified by users and should be consistent with the sharding algorithm in the sharding strategy.
ruleConfiguration.getShardingAlgorithms().put("algorithmName", new AlgorithmConfiguration("xxx", new Properties()));
```

Encryption

```java
// encryptorName is specified by users, and its property should be consistent with that of encryptorName in encryption rules.
Map<String, AlgorithmConfiguration> algorithmConfigs = new HashMap<>();
algorithmConfigs.put("encryptorName", new AlgorithmConfiguration("xxx", new Properties()));
```
Read/Write Splitting Load Balancer

// loadBalancerName is specified by users, and its property has to be consistent with that of loadBalancerName in read/write splitting rules.
Map<String, AlgorithmConfiguration> algorithmConfigs = new HashMap<>();
algorithmConfigs.put("loadBalancerName", new AlgorithmConfiguration("xxx", new Properties()));

Shadow DB

// shadowAlgorithmName is specified by users, and its property has to be consistent with that of shadowAlgorithmNames in shadow DB rules.
Map<String, AlgorithmConfiguration> algorithmConfigs = new HashMap<>();
algorithmConfigs.put("shadowAlgorithmName", new AlgorithmConfiguration("xxx", new Properties()));

High Availability

// discoveryTypeName is specified by users, and its property has to be consistent with that of discoveryTypeName in database discovery rules.
Map<String, AlgorithmConfiguration> algorithmConfigs = new HashMap<>();
algorithmConfigs.put("discoveryTypeName", new AlgorithmConfiguration("xxx", new Properties()));

Data Masking

// maskAlgorithmName is specified by users, and its property should be consistent with that of maskAlgorithm in mask rules.
Map<String, AlgorithmConfiguration> algorithmConfigs = new HashMap<>();
algorithmConfigs.put("maskAlgorithmName", new AlgorithmConfiguration("xxx", new Properties()));
9.1.3 Special API

This chapter will introduce the special API of ShardingSphere-JDBC.

Sharding

This chapter will introduce the Sharding API of ShardingSphere-JDBC.

Hint

Background

Apache ShardingSphere uses ThreadLocal to manage sharding key values for mandatory routing. A sharding value can be added by programming to the HintManager that takes effect only within the current thread.

Main application scenarios for Hint: - The sharding fields do not exist in the SQL and database table structure but in the external business logic. - Certain data operations are forced to be performed in given databases.

Procedure

1. Call HintManager.getInstance() to obtain an instance of HintManager.
2. Use HintManager.addDatabaseShardingValue, HintManager.addTableShardingValue to set the sharding key value.
3. Execute SQL statements to complete routing and execution.
4. Call HintManager.close to clean up the contents of ThreadLocal.

Sample

Hint Configuration

Hint algorithms require users to implement the interface of org.apache.shardingsphere.api.sharding.hint.HintShardingAlgorithm. Apache ShardingSphere will acquire sharding values from HintManager to route.

Take the following configurations for reference:

```
rules:
- ![SHARDING
  tables:
    t_order:
      actualDataNodes: demo_ds${0..1}.t_order_${0..1}
      databaseStrategy:
```
Get HintManager

```
HintManager hintManager = HintManager.getInstance();
```

Add Sharding Value

- Use `hintManager.addDatabaseShardingValue` to add sharding key value of data source.
- Use `hintManager.addTableShardingValue` to add sharding key value of table.

Users can use `hintManager.setDatabaseShardingValue` to set sharding value in hint route to some certain sharding database without sharding tables.

Clean Hint Values

Sharding values are saved in ThreadLocal, so it is necessary to use `hintManager.close()` to clean ThreadLocal.

```
`HintManager` has implemented ``AutoCloseable``. We recommend to close it automatically with `try with resource``.
```

Codes:

```java
// Sharding database and table with HintManager
String sql = "SELECT * FROM t_order";
try (HintManager hintManager = HintManager.getInstance();
        Connection conn = dataSource.getConnection();
        PreparedStatement preparedStatement = conn.prepareStatement(sql)) {
    hintManager.addDatabaseShardingValue("t_order", 1);
    hintManager.addTableShardingValue("t_order", 2);
    try (ResultSet rs = preparedStatement.executeQuery()) {
```
// Sharding database and one database route with HintManager
String sql = "SELECT * FROM t_order";
try (HintManager hintManager = HintManager.getInstance();
    Connection conn = dataSource.getConnection();
    PreparedStatement preparedStatement = conn.prepareStatement(sql)) {
    hintManager.setDatabaseShardingValue(3);
    try (ResultSet rs = preparedStatement.executeQuery()) {
        while (rs.next()) {
            // ...
        }
    }
}

Readwrite-splitting

This chapter will introduce the Readwrite-splitting API of ShardingSphere-JDBC.

Hint

Background

Apache ShardingSphere uses ThreadLocal to manage primary database routing marks for mandatory routing. A primary database routing mark can be added to HintManager through programming, and this value is valid only in the current thread.

Hint is mainly used to perform mandatory data operations in the primary database for read/write splitting scenarios.
Procedure

1. Call `HintManager.getInstance()` to obtain `HintManager` instance.
2. Call `HintManager.setWriteRouteOnly()` method to set the primary database routing marks.
3. Execute SQL statements to complete routing and execution.
4. Call `HintManager.close()` to clear the content of ThreadLocal.

Sample

Primary Route with Hint

Get HintManager

The same as sharding based on hint.

Configure Primary Database Route

- Use `hintManager.setWriteRouteOnly` to configure primary database route.

Clean Hint Value

The same as data sharding based on hint.

Code:

```java
String sql = "SELECT * FROM t_order";
try (HintManager hintManager = HintManager.getInstance();
     Connection conn = dataSource.getConnection();
     PreparedStatement preparedStatement = conn.prepareStatement(sql)) {
    hintManager.setWriteRouteOnly();
    try (ResultSet rs = preparedStatement.executeQuery()) {
        while (rs.next()) {
            // ...
        }
    }
}
```
Route to the specified database with Hint

Get HintManager

The same as sharding based on hint.

Configure Database Route

- Use hintManager.setDataSourceName to configure database route.

Code:

```java
String sql = "SELECT * FROM t_order";
try (HintManager hintManager = HintManager.getInstance();
    Connection conn = dataSource.getConnection();
    PreparedStatement preparedStatement = conn.prepareStatement(sql)) {
    hintManager.setDataSourceName("ds_0");
    try (ResultSet rs = preparedStatement.executeQuery()) {
        while (rs.next()) {
            // ...
        }
    }
}
```

- Core Feature: Read/write Splitting
- Developer Guide: Read/write Splitting

Transaction

Using distributed transaction through Apache ShardingSphere is no different from local transaction. In addition to transparent use of distributed transaction, Apache ShardingSphere can switch distributed transaction types every time the database accesses.

Supported transaction types include local, XA and BASE. It can be set before creating a database connection, and default value can be set when Apache ShardingSphere startup.
Use Java API

Background

With ShardingSphere-JDBC, XA and BASE mode transactions can be used through the API.

Prerequisites

Introducing Maven dependency

```xml
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-jdbc-core</artifactId>
  <version>${shardingsphere.version}</version>
</dependency>

<!-- This module is required when using XA transactions -->
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-transaction-xa-core</artifactId>
  <version>${shardingsphere.version}</version>
</dependency>

<!-- This module is required when using the Narayana mode with XA transactions -->
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-transaction-xa-narayana</artifactId>
  <version>${project.version}</version>
</dependency>

<!-- This module is required when using BASE transactions -->
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-transaction-base-seata-at</artifactId>
  <version>${shardingsphere.version}</version>
</dependency>
```
Procedure

Perform the business logic using transactions

Sample

```java
// Use ShardingSphereDataSource to get a connection and perform transaction operations.
try (Connection connection = dataSource.getConnection()) {
    connection.setAutoCommit(false);
    PreparedStatement preparedStatement = connection.prepareStatement("INSERT INTO t_order (user_id, status) VALUES (?, ?)"");
    preparedStatement.setObject(1, 1000);
    preparedStatement.setObject(2, "init");
    preparedStatement.executeUpdate();
    connection.commit();
}
```

Atomikos Transaction

Background

Apache ShardingSphere provides XA transactions, and the default XA transaction manager is Atomikos.

Procedure

1. Configure the transaction type
2. Configure Atomikos

Sample

Configure the transaction type

Yaml:

```yaml
transaction:
    defaultType: XA
    providerType: Atomikos
```
Configure Atomikos

Atomikos configuration items can be customized by adding `jta.properties` to the project’s classpath.
See Atomikos’s official documentation for more details.

Data Recovery

`xa_tx.log` is generated in the `logs` directory of the project. This is the log required for recovering XA crash. Do not delete it.

Narayana Transaction

Background

Apache ShardingSphere provides XA transactions that integrate with the Narayana implementation.

Prerequisites

Introducing Maven dependency

```xml
<properties>
  <narayana.version>5.12.4.Final</narayana.version>
  <jboss-transaction-spi.version>7.6.0.Final</jboss-transaction-spi.version>
  <jboss-logging.version>3.2.1.Final</jboss-logging.version>
</properties>

<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-jdbc-core</artifactId>
  <version>${shardingsphere.version}</version>
</dependency>

<!-- This module is required when using XA transactions -->
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-transaction-xa-core</artifactId>
  <version>${shardingsphere.version}</version>
</dependency>

<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-transaction-xa-narayana</artifactId>
  <version>${shardingsphere.version}</version>
</dependency>
```
<dependency>
  <groupId>org.jboss.narayana.jta</groupId>
  <artifactId>jta</artifactId>
  <version>${narayana.version}</version>
</dependency>
<dependency>
  <groupId>org.jboss.narayana.jts</groupId>
  <artifactId>narayana-jts-integration</artifactId>
  <version>${narayana.version}</version>
</dependency>
<dependency>
  <groupId>org.jboss</groupId>
  <artifactId>jboss-transaction-spi</artifactId>
  <version>${jboss-transaction-spi.version}</version>
</dependency>
<dependency>
  <groupId>org.jboss.logging</groupId>
  <artifactId>jboss-logging</artifactId>
  <version>${jboss-logging.version}</version>
</dependency>

**Procedure**

1. Configure Narayana
2. Set the XA transaction type

**Sample**

**Configure Narayana**

Narayana configuration items can be customized by adding jbossts-properties.xml to the project’s classpath.

See Narayana’s Official Documentation for more details.

**Set the XA transaction type**

Yaml:

```yaml
transaction:
  defaultType: XA
  providerType: Narayana
```
Seata Transaction

Background

Apache ShardingSphere provides BASE transactions that integrate the Seata implementation.

Procedure

1. Start Seata Server
2. Create the log table
3. Add the Seata configuration

Sample

Start Seata Server

Refer to seata-work-shop to download and start the Seata server.

Create undo_log table

Create the undo_log table in each shard database instance (take MySQL as an example).

```
CREATE TABLE IF NOT EXISTS `undo_log`
(
    `id` BIGINT(20) NOT NULL AUTO_INCREMENT COMMENT 'increment id',
    `branch_id` BIGINT(20) NOT NULL COMMENT 'branch transaction id',
    `xid` VARCHAR(100) NOT NULL COMMENT 'global transaction id',
    `context` VARCHAR(128) NOT NULL COMMENT 'undo_log context,such as serialization',
    `rollback_info` LONGBLOB NOT NULL COMMENT 'rollback info',
    `log_status` INT(11) NOT NULL COMMENT '0:normal status,1:defense status',
    `log_created` DATETIME NOT NULL COMMENT 'create datetime',
    `log_modified` DATETIME NOT NULL COMMENT 'modify datetime',
    PRIMARY KEY (`id`),
    UNIQUE KEY `ux_undo_log` (`xid`, `branch_id`)
) ENGINE = InnoDB
AUTO_INCREMENT = 1
DEFAULT CHARSET = utf8 COMMENT = 'AT transaction mode undo table';
```
Modify configuration

Add the seata.conf file to the classpath.

```
client {
    application.id = example  ## Apply the only primary key
    transaction.service.group = my_test_tx_group  ## The transaction group it
    belongs to.
}
```

Modify the file.conf and registry.conf files of Seata as required.

9.1.4 Optional Plugins

ShardingSphere only includes the implementation of the core SPI by default, and there is a part of the SPI that contains third-party dependencies in Git Source Implemented plugins are not included. Retrievable at https://central.sonatype.com/.

SPI and existing implementation classes of SPI corresponding to all plugins can be retrieved at https://shardingsphere.apache.org/document/current/cn/dev-manual/.

All the built-in plugins for ShardingSphere-JDBC are listed below in the form of ‘groupId:artifactId’.

- org.apache.shardingsphere:shardingsphere-authority-core, the user authority to load the logical core
- org.apache.shardingsphere:shardingsphere-cluster-mode-core, the persistent definition core of cluster mode configuration information
- org.apache.shardingsphere:shardingsphere-db-discovery-core, high availability core
- org.apache.shardingsphere:shardingsphere-encrypt-core, data encryption core
- org.apache.shardingsphere:shardingsphere-infra-context, the kernel operation and metadata refresh mechanism of Context
- org.apache.shardingsphere:shardingsphere-logging-core, logging core
- org.apache.shardingsphere:shardingsphere-mask-core, data masking core
- org.apache.shardingsphere:shardingsphere-mysql-dialect-exception, MySQL implementation of database gateway
- org.apache.shardingsphere:shardingsphere-parser-core, SQL parsing core
- org.apache.shardingsphere:shardingsphere-postgresql-dialect-exception, PostgreSQL implementation of database
- org.apache.shardingsphere:shardingsphere-readwrite-splitting-core, read-write splitting core
- org.apache.shardingsphere:shardingsphere-shadow-core, shadow library core
• org.apache.shardingsphere:shardingsphere-sharding-core, data sharding core
• org.apache.shardingsphere:shardingsphere-single-core, single-table (only the only table that exists in all sharded data sources) core
• org.apache.shardingsphere:shardingsphere-sql-federation-core, federation query executor core
• org.apache.shardingsphere:shardingsphere-sql-parser-mysql, MySQL dialect implementation of SQL parsing
• org.apache.shardingsphere:shardingsphere-sql-parser-opengauss, OpenGauss dialect implementation of SQL parsing
• org.apache.shardingsphere:shardingsphere-sql-parser-oracle, Oracle dialect implementation of SQL parsing
• org.apache.shardingsphere:shardingsphere-sql-parser-postgresql, PostgreSQL dialect implementation of SQL parsing
• org.apache.shardingsphere:shardingsphere-sql-parser-sql92, the SQL 92 dialect implementation of SQL parsing
• org.apache.shardingsphere:shardingsphere-sql-parser-sqlserver, SQL Server dialect implementation of SQL parsing
• org.apache.shardingsphere:shardingsphere-standalone-mode-core, the persistence definition core of single-machine mode configuration information
• org.apache.shardingsphere:shardingsphere-standalone-mode-repository-jdbc-h2, H2 implementation of persistent definition of configuration information in stand-alone mode
• org.apache.shardingsphere:shardingsphere-traffic-core, traffic governance core
• org.apache.shardingsphere:shardingsphere-transaction-core, XA Distributed Transaction Manager Core

If ShardingSphere-JDBC needs to use optional plugins, you need to download the JAR containing its SPI implementation and its dependent JARs from Maven Central.

All optional plugins are listed below in the form of groupId:artifactId.

• Standalone mode configuration information persistence definition
  - org.apache.shardingsphere:shardingsphere-standalone-mode-repository-jdbc-mysql, MySQL based persistence

• Cluster mode configuration information persistence definition
  - org.apache.shardingsphere:shardingsphere-cluster-mode-repository-zookeeper, Zookeeper based persistence
  - org.apache.shardingsphere:shardingsphere-cluster-mode-repository-etcd, Etcd based persistence
  - org.apache.shardingsphere:shardingsphere-cluster-mode-repository-consul, Consul based persistence
• XA transaction manager provider definition
  
  - org.apache.shardingsphere:shardingsphere-transaction-xa-narayana, XA distributed transaction manager based on Narayana

• SQL translator
  
  - org.apache.shardingsphere:shardingsphere-sql-translator-jooq-provider, JooQ SQL translator

• Row Value Expressions definition
  
  - org.apache.shardingsphere:shardingsphere-infra-expr-espresso, Row Value Expressions that uses the Groovy syntax based on GraalVM Truffle’s Espresso implementation

• Database type identification
  
  - org.apache.shardingsphere:shardingsphere-infra-database-testcontainers, Adaptation of jdbcURL for JDBC support of testcontainers-java

In addition to the above optional plugins, ShardingSphere community developers have contributed a number of plugin implementations. These plugins can be found in [ShardingSphere Plugins](https://github.com/apache/shardingsphere-plugin) repository. Plugins in ShardingSphere Plugin repository would remain the same release plan with ShardingSphere, they can be retrieved at [https://central.sonatype.com/](https://central.sonatype.com/), and install into ShardingSphere.

### 9.1.5 Unsupported Items

**DataSource Interface**

• Do not support timeout related operations

**Connection Interface**

• Do not support operations of stored procedure, function and cursor
• Do not support native SQL
• Do not support savepoint related operations
• Do not support Schema/Catalog operation
• Do not support self-defined type mapping
Statement and PreparedStatement Interface

• Do not support statements that return multiple result sets (stored procedures, multiple pieces of non-SELECT data)
• Do not support the operation of international characters

ResultSet Interface

• Do not support getting result set pointer position
• Do not support changing result pointer position through none-next method
• Do not support revising the content of result set
• Do not support acquiring international characters
• Do not support getting Array

JDBC 4.1

• Do not support new functions of JDBC 4.1 interface

For all the unsupported methods, please read org.apache.shardingsphere.driver.jdbc.unsupported package.

9.1.6 Observability

Agent

Compile source code

Download Apache ShardingSphere from GitHub, Then compile.

```
git clone --depth 1 https://github.com/apache/shardingsphere.git
cd shardingsphere
mvn clean install -DskipITs -DskipTests -Prelease
```

Artifact is distribution/agent/target/apache-shardingsphere-$(latest.release.version)-shardingsphere-agent-bin.tar.gz
Directory structure

Create agent directory, and unzip agent distribution package to the directory.

```
mkdir agent
tar -zvxvf apache-shardingsphere-${latest.release.version}-shardingsphere-agent-bin.tar.gz -C agent
cd agent
tree
├── LICENSE
├── NOTICE
├── conf
│   └── agent.yaml
├── plugins
│   ├── lib
│   │   ├── shardingsphere-agent-metrics-core-${latest.release.version}.jar
│   │   ├── shardingsphere-agent-plugin-core-${latest.release.version}.jar
│   │   └── shardingsphere-agent-plugin-core-${latest.release.version}.jar

│   └── shardingsphere-agent-logging-file-${latest.release.version}.jar
└── shardingsphere-agent-${latest.release.version}.jar
```

Agent log output location is `agent/logs/stdout.log`.

Configuration

`conf/agent.yaml` is used to manage agent configuration. Built-in plugins include File, Prometheus, OpenTelemetry.

```yaml
plugins:
  # logging:
  #   File:
  #     props:
  #       level: "INFO"
  # metrics:
  #   Prometheus:
  #     host: "localhost"
  #     port: 9090
  #     props:
  #       jvm-information-collector-enabled: "true"
  # tracing:
  #   OpenTelemetry:
  #     props:
  #       otel.service.name: "shardingsphere"
  #       otel.traces.exporter: "jaeger"
```

9.1. ShardingSphere-JDBC
# otel.exporter.otlp.traces.endpoint: "http://localhost:14250"
# otel.traces.sampler: "always_on"

## Plugin description

### File

Currently, the File plugin only outputs the time-consuming log output of building metadata, and has no other log output for the time being.

### Prometheus

Used for exposure monitoring metrics.

- Parameter description

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>host IP</td>
</tr>
<tr>
<td>port</td>
<td>port</td>
</tr>
<tr>
<td>jvm-information-collector-enabled</td>
<td>whether to collect JVM indicator information</td>
</tr>
</tbody>
</table>

### OpenTelemetry

OpenTelemetry can export tracing data to Jaeger, Zipkin.

- Parameter description

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>otel.service.name</td>
<td>service name</td>
</tr>
<tr>
<td>otel.traces.exporter</td>
<td>traces exporter</td>
</tr>
<tr>
<td>otel.exporter.otlp.traces.endpoint</td>
<td>traces endpoint</td>
</tr>
<tr>
<td>otel.traces.sampler</td>
<td>traces sampler</td>
</tr>
</tbody>
</table>

Parameter reference [OpenTelemetry SDK Autoconfigure](#)
Usage in ShardingSphere-JDBC

• 1 The SpringBoot project ready to integrate ShardingSphere-JDBC, test-project.jar
• 2 Startup project

```
java -javaagent:/agent/shardingsphere-agent-${latest.release.version}.jar -jar
  test-project.jar
```

• 3 Access to started service
• 4 Check whether the corresponding plug-in is effective

9.1.7 GraalVM Native Image

Background Information

ShardingSphere JDBC has been validated for availability under GraalVM Native Image.

ShardingSphere JDBC requires GraalVM Native Image to be built with GraalVM CE as follows or higher. Users can quickly switch JDK through SDKMAN!. Same reason applicable to downstream distributions of GraalVM CE such as Oracle GraalVM, Liberica Native Image Kit and Mandrel.

* GraalVM CE 23.0.2 For JDK 17.0.9, corresponding to 17.0.9-graalce of SDKMAN!
* GraalVM CE 23.1.1 For JDK 21.0.1, corresponding to 21.0.1-graalce of SDKMAN!

Maven Ecology

Users need to actively use the GraalVM Reachability Metadata central repository. The following configuration is for reference to configure additional Maven Profiles for the project, and the documentation of GraalVM Native Build Tools shall prevail.

```xml
<project>
  <dependencies>
    <dependency>
      <groupId>org.apache.shardingsphere</groupId>
      <artifactId>shardingsphere-jdbc-core</artifactId>
      <version>${shardingsphere.version}</version>
    </dependency>
  </dependencies>

  <build>
    <plugins>
      <plugin>
        <groupId>org.graalvm.buildtools</groupId>
        <artifactId>native-maven-plugin</artifactId>
        <version>0.9.28</version>
        <extensions>true</extensions>
        <configuration>
          <buildArgs>
            <buildArg>-H:+AddAllCharsets</buildArg>
          </buildArgs>
          <metadataRepository>
            <enabled>true</enabled>
          </metadataRepository>
        </configuration>
      </plugin>
    </plugins>
  </build>
</project>
```
<configuration>
<executions>
  <execution>
    <id>build-native</id>
    <goals>
      <goal>compile-no-fork</goal>
    </goals>
    <phase>package</phase>
  </execution>
  <execution>
    <id>test-native</id>
    <goals>
      <goal>test</goal>
    </goals>
    <phase>test</phase>
  </execution>
</executions>
</plugin>
</plugins>
</build>
</project>

**Gradle Ecosystem**

Users need to actively use the GraalVM Reachability Metadata central repository. The following configuration is for reference to configure additional Gradle Tasks for the project, and the documentation of GraalVM Native Build Tools shall prevail.

```groovy
plugins {
  id 'org.graalvm.buildtools.native' version '0.9.28'
}

dependencies {
  implementation 'org.apache.shardingsphere:shardingsphere-jdbc-core:$
  {shardingsphere.version}"
}

graalvmNative {
  binaries {
    main {
      buildArgs.add('-H:+AddAllCharsets')
    }
    test {
      buildArgs.add('-H:+AddAllCharsets')
    }
  }
  metadataRepository {
```

9.1. ShardingSphere-JDBC
For build tools such as sbt that are not supported by GraalVM Native Build Tools

Such requirements require opening additional issues at https://github.com/graalvm/native-build-tools and providing the Plugin implementation of the corresponding build tool.

Usage restrictions

1. The following algorithm classes are not available under GraalVM Native Image due to the involvement of https://github.com/oracle/graal/issues/5522.
   - org.apache.shardingsphere.sharding.algorithm.sharding.inline.InlineShardingAlgorithm
   - org.apache.shardingsphere.sharding.algorithm.sharding.inline.ComplexInlineShardingAlgorithm
   - org.apache.shardingsphere.sharding.algorithm.sharding.hint.HintInlineShardingAlgorithm

For general cases, users can simulate the behavior of GroovyShell by themselves through the CLASS_BASE algorithm. For example, take the following configuration.

```
rules:
- !SHARDING
  defaultDatabaseStrategy:
    standard:
      shardingColumn: user_id
      shardingAlgorithmName: inline
  shardingAlgorithms:
    inline:
      type: INLINE
      props:
        algorithm-expression: ds_${user_id % 2}
        allow-range-query-with-inline-sharding: false
```

You can first define the implementation class of CLASS_BASE.

```
package org.example.test;

import org.apache.shardingsphere.sharding.api.sharding.standard.PreciseShardingValue;
import org.apache.shardingsphere.sharding.api.sharding.standard.RangeShardingValue;
import org.apache.shardingsphere.sharding.api.sharding.standard.StandardShardingAlgorithm;
```
import java.util.Collection;

public final class TestShardingAlgorithmFixture implements StandardShardingAlgorithm<Integer> {

    @Override
    public String doSharding(final Collection<String> availableTargetNames, final PreciseShardingValue<Integer> shardingValue) {
        String resultDatabaseName = "ds_" + shardingValue.getValue() % 2;
        for (String each : availableTargetNames) {
            if (each.equals(resultDatabaseName)) {
                return each;
            }
        }
        return null;
    }

    @Override
    public Collection<String> doSharding(final Collection<String> availableTargetNames, final RangeShardingValue<Integer> shardingValue) {
        throw new RuntimeException("This algorithm class does not support range queries.");
    }
}

Modify the relevant YAML configuration as follows.

rules:
- !SHARDING
  defaultDatabaseStrategy:
    standard:
      shardingColumn: user_id
      shardingAlgorithmName: inline
    shardingAlgorithms:
      inline:
        type: CLASS_BASED
        props:
          strategy: STANDARD
          algorithmClassName: org.example.test.TestShardingAlgorithmFixture

Add the following content to src/main/resources/META-INF/native-image/example-test-metadata/reflect-config.json to used normally under GraalVM Native Image.

[
 {
  "name": "org.example.test.TestShardingAlgorithmFixture",
}
2. For the ReadWrite Splitting feature, you need to use other implementations of Row Value Expressions SPI to configure logic database name, writeDataSourceName and readDataSourceNames when bypassing calls to GroovyShell. One possible configuration is to use the Row Value Expressions SPI implementation of LITERAL. The same applies to actual DataNodes for the Sharding feature.

```java
rules:
- !READWRITE_SPLITTING
dataSources:
  <LITERAL>readwrite_ds:
    writeDataSourceName: <LITERAL>ds_0
    readDataSourceNames:
    - <LITERAL>ds_1
    - <LITERAL>ds_2
```

4. Maven modules such as `com.microsoft.sqlserver:mssql-jdbc`, represented by the JDBC Driver of MSSQL Server, will dynamically load different character sets based on the encoding used in the database, which is unpredictable behavior. When encountering the following Error, users need to add the `buildArg` of `-H:+AddAllCharsets` to the configuration of GraalVM Native Build Tools.

```
Caused by: java.io.UnsupportedEncodingException: SQL Server collation SQL_Latin1_General_CP1_CI_AS is not supported by this driver.
  com.microsoft.sqlserver.jdbc.SQLCollation.encodingFromSortId(SQLCollation.java:506)
  com.microsoft.sqlserver.jdbc.SQLCollation.<init>(SQLCollation.java:63)
  com.microsoft.sqlserver.jdbc.SQLServerConnection.
  processEnvChange(SQLServerConnection.java:3174)
  ...
Caused by: java.io.UnsupportedEncodingException: Codepage Cp1252 is not supported by the Java environment.
  com.microsoft.sqlserver.jdbc.Encoding.checkSupported(SQLCollation.java:572)
  com.microsoft.sqlserver.jdbc.SQLCollation$SortOrder.getEncoding(SQLCollation.
  java:473)
  com.microsoft.sqlserver.jdbc.SQLCollation.encodingFromSortId(SQLCollation.
  java:501)
  ...
```
**Contribute GraalVM Reachability Metadata**

The verification of ShardingSphere’s availability under GraalVM Native Image is completed through the Maven Plugin subproject of GraalVM Native Build Tools. By running the unit test under the JVM, label the unit test with `junit-platform-unique-ids*`, and then build it as GraalVM Native Image for `nativeTest` to test Unit Test Coverage under GraalVM Native Image. Please do not use `io.kotest:kotest-runner-junit5-jvm:5.5.4` and some third-party test libraries, they are in test listener mode failed to discover tests.

ShardingSphere defines the Maven Module of `shardingsphere-test-native` to provide a small subset of unit tests for native Test. This subset of unit tests avoids the use of third-party libraries such as Mockito that are not available under native Test.

ShardingSphere defines the Maven Profile of `nativeTestInShardingSphere` for executing `nativeTest` for the `shardingsphere-test-native` module.

Assuming that the contributor is under a new Ubuntu 22.04.3 LTS instance, Contributors can manage the JDK and toolchain through `SDKMAN!` through the following bash command, and execute `nativeTest` for the `shardingsphere-test-native` submodule.

You must install Docker Engine to execute `testcontainers-java` related unit tests.

```bash
sudo apt install unzip zip curl sed -y
curl -s "https://get.sdkman.io" | bash
source "$HOME/.sdkman/bin/sdkman-init.sh"
sdk install java 17.0.9-graalce
sdk use java 17.0.9-graalce
sudo apt-get install build-essential libz-dev zlib1g-dev -y
git clone git@github.com:apache/shardingsphere.git
cd ./shardingsphere/
./mvnw -PnativeTestInShardingSphere -T1C -e clean test
```

When contributors discover that GraalVM Reachability Metadata is missing for a third-party library not related to ShardingSphere, they should open a new issue and submit PR containing the missing third-party library GraalVM Reachability Metadata that depends on https://github.com/oracle/graalvm-reachability-metadata. ShardingSphere actively hosts the GraalVM Reachability Metadata of some third-party libraries in the `shardingsphere-infra-reachability-metadata` submodule.

If `nativeTest` execution fails, preliminary GraalVM Reachability Metadata should be generated for unit tests and manually adjusted to fix `nativeTest`. If necessary, use the `org.junit.jupiter.api.condition.DisabledInNativeImage` annotation or the `org.graalvm.nativeimage.imagecode` System Property blocks some unit tests from running under GraalVM Native Image.

ShardingSphere defines the Maven Profile of `generateMetadata`, which is used to carry GraalVM Reachability Metadata. Bring GraalVM Tracing Agent under GraalVM JIT Compiler to perform unit testing, and generate or merge existing GraalVM Reachability Metadata files in a specific directory. This process can be easily handled with the following bash command. Contributors may still need to manually adjust specific JSON entries and GraalVM Tracing Agent Filter chain of Maven Profile.

9.1. ShardingSphere-JDBC
The following command is only an example of using shardingsphere-test-native to generate GraalVM Reachability Metadata in Conditional form. Generated GraalVM Reachability Metadata is located under the shardingsphere-infra-reachability-metadata submodule.

For GraalVM Reachability Metadata used independently by test classes and test files, contributors should place ${user.dir}/infra/nativetest/src/test/resources/META-INF/native-image/shardingsphere-test-native-test-metadata/ folder. ${} contains the regular system variables of POM 4.0 corresponding to the relevant submodules, which can be replaced by yourself.

```
git clone git@github.com:apache/shardingsphere.git
cd ./shardingsphere/
./mvnw -PgenerateMetadata -DskipNativeTests -e -T1C clean test native:metadata-copy
```

Please manually delete JSON files without any specific entries.

### 9.2 ShardingSphere-Proxy

Configuration is the only module in ShardingSphere-Proxy that interacts with application developers, through which developer can quickly and clearly understand the functions provided by ShardingSphere-Proxy.

This chapter is a configuration manual for ShardingSphere-Proxy, which can also be referred to as a dictionary if necessary.

ShardingSphere-Proxy provided YAML configuration, and used DistSQL to communicate. By configuration, application developers can flexibly use data sharding, readwrite-splitting, data encryption, shadow database or the combination of them.

Rule configuration keeps consist with YAML configuration of ShardingSphere-JDBC. DistSQL and YAML can be replaced each other.

#### 9.2.1 Startup

This chapter will introduce the deployment and startup of ShardingSphere-Proxy.

**Use Binary Tar**

**Background**

This section describes how to start ShardingSphere-Proxy by binary release packages.
**Premise**

Start the Proxy with a binary package requires an environment with Java JRE 8 or later.

**Steps**

1. Obtain the binary release package of ShardingSphere-Proxy

   Obtain the binary release package of ShardingSphere-Proxy on the download page.

2. Configure conf/server.yaml

   ShardingSphere-Proxy’s operational mode is configured on server.yaml, and its configuration mode is the same with that of ShardingSphere-JDBC. Refer to mode of configuration.

   Please refer to the following links for other configuration items: * Permission configuration * Property configuration

3. Configure conf/config-*.yaml

   Modify files named with the prefix config- in the conf directory, such as conf/config-sharding.yaml file and configure sharding rules and read/write splitting rules. See Configuration Manual for configuration methods. The * part of the config-*.yaml file can be named whatever you want.

   ShardingSphere-Proxy supports multiple logical data sources. Each YAML configuration file named with the prefix config- is a logical data source.

4. Introduce database driver (Optional)

   If the backend is connected to a PostgreSQL or openGauss database, no additional dependencies need to be introduced.

   If the backend is connected to a MySQL database, please download mysql-connector-java-5.1.49.jar or mysql-connector-java-8.0.11.jar, and put it into the ext-lib directory.

5. Introduce dependencies required by the cluster mode (Optional)

   ShardingSphere-Proxy integrates the ZooKeeper Curator client by default. ZooKeeper is used in cluster mode without introducing other dependencies.

   If the cluster mode uses Etcd, the client drivers of Etcd jetcd-core 0.7.3 need to be copied into the ext-lib directory.

6. Introduce dependencies required by distributed transactions (Optional)

   It is the same with ShardingSphere-JDBC. Please refer to Distributed Transaction for more details.

7. Introduce custom algorithm (Optional)

   If you need to use a user-defined algorithm class, you can configure custom algorithm in the following ways:

   1. Implement the algorithm implementation class defined by 'ShardingAlgorithm'.
   2. Create a `META-INF/services` directory under the project `resources` directory.
   3. Create file `org.apache.shardingsphere.sharding.spi.ShardingAlgorithm` under the
directory `META-INF/services`.
4. Writes the fully qualified class name of the implementation class to a file `org.apache.shardingsphere.sharding.spi.ShardingAlgorithm`
5. Package the above Java files into jar packages.
6. Copy the above jar package to the `ext-lib` directory.

8. Start ShardingSphere-Proxy

In Linux or macOS, run `bin/start.sh`. In Windows, run `bin/start.bat` to start ShardingSphere-Proxy. The default listening port is 3307 and the default configuration directory is the `conf` directory in Proxy. The startup script can specify the listening port and the configuration file directory by running the following command:

```bash
bin/start.sh [port] [/path/to/conf]
```

9. Connect ShardingSphere-Proxy with client

Run the MySQL/PostgreSQL/openGauss client command to directly operate ShardingSphere-Proxy.

Connect ShardingSphere-Proxy with MySQL client:

```bash
mysql -h${proxy_host} -P${proxy_port} -u${proxy_username} -p${proxy_password}
```

Connect ShardingSphere-Proxy with PostgreSQL:

```bash
psql -h ${proxy_host} -p ${proxy_port} -U ${proxy_username}
```

Connect ShardingSphere-Proxy with openGauss client:

```bash
gsql -r -h ${proxy_host} -p ${proxy_port} -U ${proxy_username} -W ${proxy_password}
```
Use Docker

Background

This chapter is an introduction about how to start ShardingSphere-Proxy via Docker

Notice

Using Docker to start ShardingSphere-Proxy does not require additional package support.

Steps

1. Acquire Docker Image
   - Method 1 (Recommended): Pull from DockerHub
     docker pull apache/shardingsphere-proxy
   - Method 3: Build your own image
     git clone https://github.com/apache/shardingsphere
     ./mvnw clean install
     cd shardingsphere-distribution/shardingsphere-proxy-distribution
     ./mvnw clean package -Prelease,docker

     If the following problems emerge, please make sure Docker daemon Process is running.

     I/O exception (java.io.IOException) caught when processing request to {}->unix://localhost:80: Connection refused?

2. Configure conf/server.yaml and conf/config-* .yaml

   Configuration file template can be attained from the Docker container and can be copied to any directory on the host:

   docker run -d --name tmp --entrypoint=bash apache/shardingsphere-proxy
   docker cp tmp:/opt/shardingsphere-proxy/conf /host/path/to/conf
   docker rm tmp

   Since the network conditions inside the container may differ from those of the host, if errors such as “cannot connect to the database” occurs, please make sure that the IP of the database specified in the conf/config-* .yaml configuration file can be accessed from inside the Docker container.

   For details, please refer to ShardingSphere-Proxy quick start manual - binary distribution packages.

3. (Optional) Introduce third-party dependencies or customized algorithms
If you have any of the following requirements: * ShardingSphere-Proxy Backend use MySQL Database; * Implement customized algorithms; * Use Etcd as Registry Center in cluster mode.

Please create ext-lib directory anywhere inside the host and refer to the steps in ShardingSphere-Proxy quick start manual - binary distribution packages.

4. Start ShardingSphere-Proxy container

Mount the conf and ext-lib directories from the host to the container. Start the container:

```bash
docker run -d \
  -v /host/path/to/conf:/opt/shardingsphere-proxy/conf \
  -v /host/path/to/ext-lib:/opt/shardingsphere-proxy/ext-lib \
  -e PORT=3308 -p13308:3308 apache/shardingsphere-proxy:latest
```

ext-lib is not necessary during the process. Users can mount it at will. ShardingSphere-Proxy default portal 3307 can be designated according to environment variable -e PORT Customized JVM related parameters can be set according to environment variable JVM_OPTS

Note:

Support setting environment variable CGROUP_MEM_OPTS: used to set related memory parameters in the container environment. The default values in the script are:

```
-XX:InitialRAMPercentage=80.0 -XX:MaxRAMPercentage=80.0 -XX:MinRAMPercentage=80.0
```

5. Use Client to connect to ShardingSphere-Proxy

Please refer to ShardingSphere-Proxy quick start manual · binary distribution packages.

Build GraalVM Native Image (Alpha)

**Background**

This section mainly introduces how to build the Native Image of ShardingSphere-Proxy and the corresponding Docker Image through the native-image component of GraalVM.

**Notice**

- ShardingSphere Proxy is not yet ready to integrate with GraalVM Native Image. Proxy’s Native Image artifacts are built nightly at https://github.com/apache/shardingsphere/pkg/container/shardingsphere-proxy-native. Assuming there is a conf folder containing server.yaml as ./custom/conf, you can test it with the following docker-compose.yml file.

```
version: "3.8"

services:
  apache-shardingsphere-proxy-native:
    image: ghcr.io/apache/shardingsphere-proxy-native:latest
    volumes:
```

9.2. ShardingSphere-Proxy
- ./custom/conf:/opt/shardingsphere-proxy-native/conf
ports:
  - "3307:3307"

• This section assumes a Linux (amd64, aarch64), MacOS (amd64) or Windows (amd64) environment. If you are on MacOS (aarch64/M1) environment, you need to follow https://github.com/oracle/graal/issues/2666 which is not closed yet.

Premise

1. Install and configure GraalVM Community Edition or a downstream distribution of GraalVM Community Edition for JDK 17 according to https://www.graalvm.org/downloads/. If SDKMAN! is used,

   sdk install java 17.0.9-graalce

3. If you need to build a Docker Image, make sure docker-ce is installed.

Steps

1. Get Apache ShardingSphere Git Source
   - Get it at the download page or https://github.com/apache/shardingsphere/tree/master.

2. Build the product on the command line, in two cases.
   - Scenario 1: No need to use JARs with SPI implementations or 3rd party dependencies
     • Execute the following command in the same directory of Git Source to directly complete the construction of Native Image.

     ./mvnw -am -pl distribution/proxy-native -B -T1C -Prelease.native -DskipTests clean package

     • Scenario 2: It is necessary to use a JAR that has an SPI implementation or a third-party dependent JAR of a LICENSE such as GPL V2.
     • Add SPI implementation JARs or third-party dependent JARs to dependencies in distribution/proxy-native/pom.xml. Examples are as follows

<dependencies>
   <dependency>
     <groupId>com.mysql</groupId>
     <artifactId>mysql-connector-j</artifactId>
     <version>8.1.0</version>
   </dependency>
</dependencies>
• Build GraalVM Native Image via command line.

```bash
./mvnw -am -pl distribution/proxy-native -B -T1C -Prelease.native -DskipTests clean package
```

3. To start Native Image through the command line, you need to bring 4 parameters. The first parameter is the Port used by ShardingSphere Proxy, the second parameter is the /conf folder containing `server.yaml` written by you, the third parameter is the Address of the bound port, and the fourth parameter is Force Start, if it is true, it will ensure that ShardingSphere Proxy Native can start normally no matter whether it is connected or not. Assuming the folder `./custom/conf` already exists, the example is

```bash
./apache-shardingsphere-proxy-native 3307 ./custom/conf "0.0.0.0" false
```

4. If you need to build a Docker Image, execute the following command on the command line after adding dependencies that exist for SPI implementation or third-party dependencies.

```bash
./mvnw -am -pl distribution/proxy-native -B -T1C -Prelease.native,docker.native -DskipTests clean package
```

• Assuming that there is a `conf` folder containing `server.yaml` as `./custom/conf`, you can start the Docker Image corresponding to GraalVM Native Image through the following `docker-compose.yml` file.

```yaml
version: "3.8"

services:
  apache-shardingsphere-proxy-native:
    image: apache/shardingsphere-proxy-native:latest
    volumes:
      - ./custom/conf:/opt/shardingsphere-proxy-native/conf
    ports:
      - "3307:3307"
```

• If you don’t make any changes to the Git Source, the commands mentioned above will use `oraclelinux:9-slim` as the Base Docker Image. But if you want to use a smaller Docker Image like `busybox:glic`, `gcr.io/distroless/base` or `scratch` as the Base Docker Image, you need according to https://www.graalvm.org/jdk17/reference-manual/native-image/guides/build-static-executables/, add operations such as `-H:+StaticExecutableWithDynamicLibC` to `jvmArgs` as the native profile of pom.xml. Also note that some 3rd-party dependencies will require more system libraries such as `libdl` to be installed in the Dockerfile. So make sure to
tune distribution/proxy-native according to your usage pom.xml and Dockerfile below.

**Observability**

- You can observe GraalVM Native Image using a series of command line tools or visualization tools available at https://www.graalvm.org/jdk17/tools/, and use VSCode to debug it according to its requirements. If you are using IntelliJ IDEA and want to debug the generated GraalVM Native Image, You can follow https://blog.jetbrains.com/idea/2022/06/intellij-idea-2022-2-eap-5/#Experimental_GraalVM_Native_Debugger_for_Java and its successors. If you are not using Linux, you cannot debug GraalVM Native Image, please pay attention to https://github.com/oracle/graal/issues/5648 which has not been closed yet.

- In the case of using APM Java Agent such as ShardingSphere Agent, GraalVM’s native-image component is not yet fully supported when building Native Images javaagent, you need to follow https://github.com/oracle/graal/issues/1065 which has not been closed.

- The following sections use the Apache SkyWalking Java Agent as an example, which can be used to track corresponding issues from the GraalVM community.

- If users expect to use OpenTelemetry Java Agent under ShardingSphere Proxy Native, they need to pay attention to the changes involved in https://github.com/oracle/graal/pull/8077.

**Use Helm**

**Background**

Use Helm to provide guidance for the installation of ShardingSphere-Proxy instance in a Kubernetes cluster. For more details, please checkout ShardingSphere-on-Cloud.

**Requirements**

- Kubernetes 1.18+
- kubectl
- Helm 3.2.0+
- StorageClass of PV (Persistent Volumes) can be dynamically applied for persistent data (Optional)
**Procedure**

**Online installation**

1. Add ShardingSphere-Proxy to the local helm repo:

```bash
ehelm repo add shardingsphere https://shardingsphere.apache.org/charts
```

2. Install ShardingSphere-Proxy charts:

```bash
ehelm install shardingsphere-proxy shardingsphere/shardingsphere-proxy
```

**Source installation**

1. Charts will be installed with default configuration if the following commands are executed:

```bash
git clone https://github.com/apache/shardingsphere-on-cloud.git
cd charts/shardingsphere-proxy/charts/governance
helm dependency build
cd ../..
helm dependency build
cd..
helm install shardingsphere-proxy shardingsphere-proxy
```

**Note:**

1. Please refer to the configuration items description below for more details:
2. Execute `helm list` to acquire all installed releases.

**Uninstall**

1. Delete all release records by default, add `--keep-history` to keep them.

```bash
ehelm uninstall shardingsphere-proxy
```

**Parameters**

**Governance-Node parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Value</th>

### Add dependencies

This chapter mainly introduces how to download optional dependencies of ShardingSphere.

### Add Narayana dependencies

Adding Narayana dependencies requires downloading the following jar files and adding them under `ext-lib` path.
jar file downloads

- arjuna-5.12.4.Final.jar
- common-5.12.4.Final.jar
- jboss-connector-api_1.7_spec-1.0.0.Final.jar
- jboss-logging-3.2.1.Final.jar
- jboss-transaction-api_1.2_spec-1.0.0.Alpha3.jar
- jboss-transaction-spi-7.6.0.Final.jar
- jta-5.12.4.Final.jar
- narayana-jts-integration-5.12.4.Final.jar
- shardingsphere-transaction-xa-narayana.jar

Please download the corresponding shardingsphere-transaction-xa-narayana.jar file according to the proxy version.

9.2.2 Yaml Configuration

The YAML configuration of ShardingSphere-JDBC is the subset of ShardingSphere-Proxy. In server.yaml file, ShardingSphere-Proxy can configure authority feature and more properties for Proxy only.

Note: The YAML configuration file supports more than 3MB of configuration content.

This chapter will introduce the extra YAML configuration of ShardingSphere-Proxy.

Authentication & Authorization

Background

In ShardingSphere-Proxy, user authentication and authorization information is configured through authority.

Thanks to ShardingSphere’s pluggable architecture, Proxy provides two levels of privilege providers, namely:

- **ALL_PERMITTED**: each user has all privileges without special authorization.
- **DATABASE_PERMITTED**: grants the user privileges on the specified logical databases, defined by user-database-mappings.

The administrator can choose which privilege provider to use as needed when configuring authority.
Parameters

```yaml
authority:
  users:
    - user: # Specify the username, and authorized host for logging in to the compute node. Format: <username>@<hostname>. When the hostname is % or an empty string, it indicates that the authorized host is not limited.
      password: # Password
      authenticationMethodName: # Optional, used to specify the password authentication method for the user
      authenticators: # Optional, not required by default, Proxy will automatically choose the authentication method according to the frontend protocol type
        authenticatorName:
          type: # Authentication method type
          defaultAuthenticator: # Optional, specify an authenticator as the default password authentication method
          privilege:
            type: # Privilege provider type. The default value is ALL_PERMITTED.
```

Sample

Minimalist configuration

```yaml
authority:
  users:
    - user: root@
      password: root
    - user: sharding
      password: sharding
```

Explanation: · Two users are defined: root@% and sharding; · authenticationMethodName is not specified for root@127.0.0.1, Proxy will automatically choose the authentication method according to the frontend protocol; · Privilege provider is not specified, the default ALL_PERMITTED will be used;

Authentication configuration

The custom authentication configuration allows users to greater leeway to set their own custom configurations according to their scenarios. Taking openGauss as the frontend protocol type as an example, its default authentication method is scram-sha-256. If the user sharding needs to use an old version of the psql client (which does not support scram-sha-256) to connect to the Proxy, the administrator may allow sharding to use the md5 method for password authentication. The configuration is as follows:

```yaml
authority:
  users:
```
- user: root@127.0.0.1
  password: root
- user: sharding
  password: sharding
  authenticationMethodName: md5
authenticators:
  md5:
    type: MD5
privilege:
  type: ALL_PERMITTED

Explanation: - Two users are defined: root@127.0.0.1 and sharding; - Use MD5 method for password authentication for sharding; - Authentication method is not specified for root@127.0.0.1, Proxy will automatically choose one according to the frontend protocol; - The privilege provider ALL_PERMITTED is specified.

### Authorization configuration

**ALL_PERMITTED**

```yaml
authority:
  users:
    - user: root@127.0.0.1
      password: root
    - user: sharding
      password: sharding
  privilege:
    type: ALL_PERMITTED
```

Explanation: - Two users are defined: root@127.0.0.1 and sharding; - authenticators and authenticationMethodName are not defined, Proxy will automatically choose the authentication method according to the frontend protocol; - The privilege provider ALL_PERMITTED is specified.

**DATABASE_PERMITTED**

```yaml
authority:
  users:
    - user: root@127.0.0.1
      password: root
    - user: sharding
      password: sharding
  privilege:
    type: DATABASE_PERMITTED
```
user-database-mappings: root@127.0.0.1=*, sharding@%=test_db, sharding@%=sharding_db

Explanation: - Two users are defined: root@127.0.0.1 and sharding; - authenticators and authenticationMethodName are not defined, Proxy will automatically choose the authentication method according to the frontend protocol; - The privilege provider DATABASE_PERMITTED is specified, authorize root@127.0.0.1 to access all logical databases (*), and user sharding can only access test_db and sharding_db.

Related References

Please refer to Authority Provider for the specific implementation of authority provider.

Properties

Background

Apache ShardingSphere provides a wealth of system configuration properties, which users can configure through server.yaml.
Parameters

<table>
<thead>
<tr>
<th>Name*</th>
<th>DataType*</th>
<th>Description</th>
<th>Default*</th>
<th>DynamicUpdate*</th>
</tr>
</thead>
<tbody>
<tr>
<td>system-log-level (?)</td>
<td>String</td>
<td>System log output level, supports DEBUG, INFO, WARN and ERROR, the default level is INFO.</td>
<td>false</td>
<td>True</td>
</tr>
<tr>
<td>sql-show (?)</td>
<td>boolean</td>
<td>Whether to print SQL in logs. Printing SQL can help developers quickly locate system problems. Logs contain the following contents: logical SQL, authentic SQL and SQL parsing result. If configuration is enabled, logs will use Topic ShardingSphere-SQL, and log level is INFO.</td>
<td>false</td>
<td>True</td>
</tr>
<tr>
<td>sql-simple (?)</td>
<td>boolean</td>
<td>Whether to print simple SQL in logs.</td>
<td>false</td>
<td>True</td>
</tr>
<tr>
<td>kernel-exuctor-size (?)</td>
<td>int</td>
<td>Set the size of the thread pool for task processing. Each ShardingSphere-DataSource uses an independent thread pool, and different data sources on the same JVM do not share thread pools.</td>
<td>infinite</td>
<td>False</td>
</tr>
</tbody>
</table>

9.2. ShardingSphere-Proxy

<table>
<thead>
<tr>
<th>Name*</th>
<th>DataType*</th>
<th>Description</th>
<th>Default*</th>
<th>DynamicUpdate*</th>
</tr>
</thead>
<tbody>
<tr>
<td>max-connections-size-per-proxy</td>
<td>int</td>
<td>The maximum number of connection per proxy.</td>
<td>1</td>
<td>True</td>
</tr>
</tbody>
</table>
Properties can be modified online through DistSQL#RAL. Properties that support dynamic change can take effect immediately. For the ones that do not support dynamic change, the effect will be implemented after a restart.

Sample

For a complete sample, please refer to server.yaml in ShardingSphere’s repository: [https://github.com/apache/shardingsphere/blob/aac0d3026e00575114701be603ec189a02a45747/shardingsphere-proxy/shardingsphere-proxy-bootstrap/src/main/resources/conf/server.yaml#L71-L93](https://github.com/apache/shardingsphere/blob/aac0d3026e00575114701be603ec189a02a45747/shardingsphere-proxy/shardingsphere-proxy-bootstrap/src/main/resources/conf/server.yaml#L71-L93)

Rules

Background

This section explains how to configure the ShardingSphere-Proxy rules.

Parameters Explained

Rules configuration for ShardingSphere-Proxy is the same as ShardingSphere-JDBC. For details, please refer to ShardingSphere-JDBC Rules Configuration.

Notice

Unlike ShardingSphere-JDBC, the following rules need to be configured in ShardingSphere-Proxy’s server.yaml:

- **SQL Parsing**

```yaml
sqlParser:
  sqlStatementCache:
    initialCapacity: 2000
    maximumSize: 65535
  parseTreeCache:
    initialCapacity: 128
    maximumSize: 1024
```

- **Distributed Transaction**

```yaml
transaction:
  defaultType: XA
  providerType: Atomikos
```

- **SQL Translator**

9.2. ShardingSphere-Proxy
sqlTranslator:
  type:
  useOriginalSQLWhenTranslatingFailed:

Data Source

Background

ShardingSphere-Proxy supports common data source connection pools: HikariCP, C3P0, DBCP (C3P0, DBCP need download plugin from shardingSphere-plugins repository). The connection pool can be specified through the parameter dataSourceClassName. When not specified, the default data source connection pool is HikariCP.

Parameters

dataSources: # Data sources configuration, multiple <data-source-name> available
  <data_source_name>: # Data source name
    dataSourceClassName: # Data source connection pool full class name
    url: # The database URL connection
    username: # Database username
    password: # The database password
    # ... Other properties of data source pool

Sample

dataSources:
  ds_1:
    url: jdbc:mysql://localhost:3306/ds_1
    username: root
    password:
  ds_2:
    dataSourceClassName: com.mchange.v2.c3p0.ComboPooledDataSource
    url: jdbc:mysql://localhost:3306/ds_2
    username: root
    password:
  ds_3:
    dataSourceClassName: org.apache.commons.dbcp2.BasicDataSource
    username: root
    password:

  # Configure other data sources
9.2.3 DistSQL

This chapter will introduce the detailed syntax of DistSQL.

**Definition**

DistSQL (Distributed SQL) is Apache ShardingSphere’s specific SQL, providing additional operation capabilities compared to standard SQL.

Flexible rule configuration and resource management & control capabilities are one of the characteristics of Apache ShardingSphere.

When using 4.x and earlier versions, developers can operate data just like using a database, but they need to configure resources and rules through YAML file (or registry center). However, the YAML file format and the changes brought by using the registry center made it unfriendly to DBAs.

Starting from version 5.x, DistSQL enables users to operate Apache ShardingSphere just like a database, transforming it from a framework and middleware for developers to a database product for DBAs.

**Related Concepts**

DistSQL is divided into RDL, RQL, RAL and RUL.

**RDL**

Resource & Rule Definition Language, is responsible for the definition of resources and rules.

**RQL**

Resource & Rule Query Language, is responsible for the query of resources and rules.

**RAL**

Resource & Rule Administration Language, is responsible for hint, circuit breaker, configuration import and export, scaling control and other management functions.

**RUL**

Resource & Rule Utility Language, is responsible for SQL parsing, SQL formatting, preview execution plan, etc.
Impact on the System

Before

Before having DistSQL, users used SQL to operate data while using YAML configuration files to manage ShardingSphere, as shown below:

At that time, users faced the following problems: - Different types of clients are required to operate data and manage ShardingSphere configuration. - Multiple logical databases require multiple YAML files. - Editing a YAML file requires writing permissions. - Need to restart ShardingSphere after editing YAML.

After

With the advent of DistSQL, the operation of ShardingSphere has also changed:

Now, the user experience has been greatly improved: - Uses the same client to operate data and ShardingSphere configuration. - No need for additional YAML files, and the logical databases are managed through DistSQL. - Editing permissions for files are no longer required, and configuration is managed
through DistSQL. Configuration changes take effect in real-time without restarting ShardingSphere.

Limitations

DistSQL can be used only with ShardingSphere-Proxy, not with ShardingSphere-JDBC for now.

How it works

Like standard SQL, DistSQL is recognized by the parsing engine of ShardingSphere. It converts the input statement into an abstract syntax tree and then generates the Statement corresponding to each grammar, which is processed by the appropriate Handler.

Related References

User Manual: DistSQL

Syntax

This chapter describes the syntax of DistSQL in detail, and introduces use of DistSQL with practical examples.
### Syntax Rule

In DistSQL statement, except for keywords, the input format of other elements shall conform to the following rules.

#### Identifier

1. The identifier represents an object in the SQL statement, including:
   - database name
   - table name
   - column name
   - index name
   - resource name
   - rule name
   - algorithm name
2. The allowed characters in the identifier are: `[a-zA-Z, 0-9, _]` (letters, numbers, underscores) and should start with a letter.
3. When keywords or special characters appear in the identifier, use the backticks (').

#### Literal

Types of literals include:

- string: enclosed in single quotes (’) or double quotes (“)
- int: it is generally a positive integer, such as 0-9;

Note: some DistSQL syntax allows negative values. In this case, a negative sign (-) can be added before the number, such as -1.

- boolean, containing only true & false. Case insensitive.

#### Special Instructions

- The "" must be used to mark the algorithm type name when specifying a user-defined algorithm type name, for example, `NAME=AlgorithmTypeName`
- The "" is not necessary when specifying a ShardingSphere Built-in algorithm type name, for example, `NAME=HASH_MOD`
RDL Syntax

RDL (Resource & Rule Definition Language) responsible for definition of resources/rules.

Storage Unit Definition

This chapter describes the syntax of storage unit.

REGISTER STORAGE UNIT

Description

The REGISTER STORAGE UNIT syntax is used to register storage unit for the currently selected logical database.

Syntax

```
RegisterStorageUnit ::= 'REGISTER' 'STORAGE' 'UNIT' ifNotExists? storageUnitDefinition (',',
storageUnitDefinition)*

storageUnitDefinition ::= storageUnitName '(' ('HOST' '=' hostName ', 'PORT' '=' port ', 'DB' '=' dbName |
'URL' '=' url ', 'USER' '=' user ',' 'PASSWORD' '=' password)? (',,
propertiesDefinition)?)

ifNotExists ::= 'IF' 'NOT' 'EXISTS'

storageUnitName ::= identifier

hostname ::= string

port ::= int

dbName ::= string

url ::= string

user ::= string
```
**Supplement**

- Before register storage units, please confirm that a database has been created in Proxy, and execute the use command to successfully select a database;
- Confirm that the registered storage unit can be connected normally, otherwise it will not be added successfully;
- `storageUnitName` is case-sensitive;
- `storageUnitName` needs to be unique within the current database;
- `storageUnitName` name only allows letters, numbers and `_`, and must start with a letter;
- `poolProperty` is used to customize connection pool parameters, key must be the same as the connection pool parameter name;
- `ifNotExists` clause is used for avoid Duplicate storage unit error.

**Example**

- Register storage unit using standard mode

```sql
REGISTER STORAGE UNIT ds_0 (  
  HOST="127.0.0.1",  
  PORT=3306,  
  DB="db_1",  
  USER="root",  
  PASSWORD="root"  
);  
```

- Register storage unit and set connection pool parameters using standard mode

```sql
REGISTER STORAGE UNIT ds_0 (  
  HOST="127.0.0.1",  
  
```
PORT=3306,
DB="db_1",
USER="root",
PASSWORD="root",
PROPERTIES("maximumPoolSize"=10)
);

- Register storage unit and set connection pool parameters using URL patterns

REGISTER STORAGE UNIT ds_0 (
    URL="jdbc:mysql://127.0.0.1:3306/db_2?serverTimezone=UTC&useSSL=false",
    USER="root",
    PASSWORD="root",
    PROPERTIES("maximumPoolSize"=10,"idleTimeout"="30000")
);

- Register storage unit with ifNotExists clause

REGISTER STORAGE UNIT IF NOT EXISTS ds_0 ( 
    HOST="127.0.0.1",
    PORT=3306,
    DB="db_0",
    USER="root",
    PASSWORD="root"
);

Reserved word

REGISTER, STORAGE, UNIT, HOST, PORT, DB, USER, PASSWORD, PROPERTIES, URL

- Reserved word

ALTER STORAGE UNIT

Description

The ALTER STORAGE UNIT syntax is used to alter storage units for the currently selected logical database.
### Syntax

```
AlterStorageUnit ::= 'ALTER' 'STORAGE' 'UNIT' storageUnitDefinition (',' storageUnitDefinition)*
```

```
storageUnitDefinition ::= storageUnitName '(' ('HOST' '=' hostName ',' 'PORT' '=' port ',' 'DB' '=' dbName | 'URL' '=' url ) ',' 'USER' '=' user (',' 'PASSWORD' '=' password)? (',' propertiesDefinition)? ')
```

```
storageUnitName ::= identifier
```

```
hostname ::= string
```

```
port ::= int
```

```
dbName ::= string
```

```
url ::= string
```

```
user ::= string
```

```
password ::= string
```

```
propertiesDefinition ::= 'PROPERTIES' '(' key '=' value (',' key '=' value)* ')'
```

```
key ::= string
```

```
value ::= literal
```
Supplement

- Before altering the storage units, please confirm that a database exists in Proxy, and execute the `use` command to successfully select a database;
- `ALTER STORAGE UNIT` is not allowed to change the real data source associated with this storage Unit;
- `ALTER STORAGE UNIT` will switch the connection pool. This operation may affect the ongoing business, please use it with caution;
- `storageUnitName` is case-sensitive;
- `storageUnitName` needs to be unique within the current database;
- `storageUnitName` name only allows letters, numbers and [_], and must start with a letter;
- `poolProperty` is used to customize connection pool parameters, key must be the same as the connection pool parameter name.

Example

- Alter storage unit using standard mode

```sql
ALTER STORAGE UNIT ds_0 (  
    HOST=127.0.0.1,  
    PORT=3306,  
    DB=db_0,  
    USER=root,  
    PASSWORD=root  
);
```

- Alter storage unit and set connection pool parameters using standard mode

```sql
ALTER STORAGE UNIT ds_0 (  
    HOST=127.0.0.1,  
    PORT=3306,  
    DB=db_1,  
    USER=root,  
    PASSWORD=root  
    PROPERTIES("maximumPoolSize"=10)  
);
```

- Alter storage unit and set connection pool parameters using URL patterns

```sql
ALTER STORAGE UNIT ds_0 (  
    URL="jdbc:mysql://127.0.0.1:3306/db_2?serverTimezone=UTC&useSSL=false",  
    USER=root,  
    PASSWORD=root,  
    PROPERTIES("maximumPoolSize"=10,"idleTimeout"="30000")  
);
```

UNREGISTER STORAGE UNIT

Description

The UNREGISTER STORAGE UNIT syntax is used to unregister storage unit from the current database

Syntax

UnregisterStorageUnit ::=  
   'UNREGISTER' 'STORAGE' 'UNIT' ifExists? storageUnitName (',' storageUnitName)*  
   (ignoreSingleTables | ignoreBroadcastTables | ignoreSingleAndBroadcastTables)?

ignoreSingleTables ::=  
   'IGNORE' 'SINGLE' 'TABLES'

ignoreBroadcastTables ::=  
   'IGNORE' 'BROADCAST' 'TABLES'

ignoreSingleAndBroadcastTables ::=  
   'IGNORE' ('SINGLE' ',' 'BROADCAST' | 'BROADCAST' ',' 'SINGLE') 'TABLES'

ifExists ::=  
   'IF' 'EXISTS'

storageUnitName ::=  
   identifier

Supplement

- UNREGISTER STORAGE UNIT will only unregister storage unit in Proxy, the real data source corresponding to the storage unit will not be unregistered;
- Unable to unregister storage unit already used by rules. Storage unit are still in used. will be prompted when removing storage units used by rules;
- The storage unit need to be removed only contains SINGLE RULE, BROADCAST RULE and when the user confirms that this restriction can be ignored, the IGNORE SINGLE TABLES, IGNORE
BROADCAST TABLES, IGNORE SINGLE, BROADCAST TABLES keyword can be added to remove the storage unit;

- ifExists clause is used for avoid Storage unit not exists error.

Example

- Drop a storage unit

```sql
UNREGISTER STORAGE UNIT ds_0;
```

- Drop multiple storage units

```sql
UNREGISTER STORAGE UNIT ds_0, ds_1;
```

- Ignore single rule remove storage unit

```sql
UNREGISTER STORAGE UNIT ds_0 IGNORE SINGLE TABLES;
UNREGISTER STORAGE UNIT ds_0 IGNORE BROADCAST TABLES;
UNREGISTER STORAGE UNIT ds_0 IGNORE SINGLE, BROADCAST TABLES;
```

- Drop the storage unit with ifExists clause

```sql
UNREGISTER STORAGE UNIT IF EXISTS ds_0;
```

Rule Definition

This chapter describes the syntax of rule definition.
This chapter describes the syntax of sharding.

**CREATE SHARDING TABLE RULE**

**Description**

The `CREATE SHARDING TABLE RULE` syntax is used to add sharding table rule for the currently selected database.

**Syntax**

```
CreateShardingTableRule ::= 
  'CREATE' 'SHARDING' 'TABLE' 'RULE' ifNotExists? (tableDefinition | 
  autoTableDefinition) (',' (tableDefinition | autoTableDefinition))*
```

```
ifNotExists ::= 
  'IF' 'NOT' 'EXISTS'
```

```
tableDefinition ::= 
  tableName ('DATANODES' (' dataNode (',' dataNode)* ')=(' DATABASE_ 
  STRATEGY ' strategyDefinition ')? (',' 'TABLE_STRATEGY' '(' 
  strategyDefinition ')')? (',' 'KEY_GENERATE_STRATEGY' '(' 
  keyGenerateStrategyDefinition ')')? (',' 'AUDIT_STRATEGY' '(' 
  auditStrategyDefinition ')')?
```

```
autoTableDefinition ::= 
  tableName ('STORAGE_UNITS' (' storageUnitName (',' storageUnitName)* ')=', 
  'SHARDING_COLUMN' '=' columnName ',', algorithmDefinition ('KEY_GENERATE_ 
  STRATEGY ' keyGenerateStrategyDefinition ')? (',' 'AUDIT_STRATEGY' '(' 
  auditStrategyDefinition ')')?
```

```
strategyDefinition ::= 
  'TYPE' '=' strategyType ',' ('SHARDING_COLUMN' | 'SHARDING_COLUMNS') '=' 
  columnName ',', algorithmDefinition
```

```
keyGenerateStrategyDefinition ::= 
  'KEY_GENERATE_STRATEGY' '(' 'COLUMN' '=' columnName ',', algorithmDefinition ')
```

```
auditStrategyDefinition ::= 
  'AUDIT_STRATEGY' '(' algorithmDefinition (',' algorithmDefinition)* ')
```

```
algorithmDefinition ::= 
  'TYPE' '(' 'NAME' '=' algorithmType (',' propertiesDefinition)? ')' 
```
propertiesDefinition ::= 'PROPERTIES' ( 'key' '=' value (', ' key '=>' value)* ')'

key ::= string

value ::= literal

tableName ::= identifier

dataNode ::= string

storageUnitName ::= identifier

colonName ::= identifier

algorithmType ::= identifier

strategyType ::= string

Supplement

• tableName is defined for standard sharding table rule; autoTableDefinition is defined for auto sharding table rule. For standard sharding rules and auto sharding rule, refer to Data Sharding;

• use standard sharding table rule:
  – DATANODES can only use resources that have been added to the current database, and can only use INLINE expressions to specify required resources;
  – DATABASE_STRATEGY, TABLE_STRATEGY are the database sharding strategy and the table sharding strategy, which are optional, and the default strategy is used when not configured;
  – The attribute TYPE in strategyDefinition is used to specify the type of Sharding Algorithm, currently only supports STANDARD, COMPLEX. Using COMPLEX requires specifying multiple sharding columns with SHARDING_COLUMNS.

• use auto sharding table rule:
  – STORAGE_UNITS can only use storage units that have been registered to the current database, and the required storage units can be specified by enumeration or INLINE expres-
Only auto-sharding algorithm can be used, please refer to Auto Sharding Algorithm.

- `algorithmType` is the sharding algorithm type, please refer to Sharding Algorithm;
- The auto-generated algorithm naming rule is `tableName_`_`strategyType`_`shardingAlgorithmType`;
- The auto-generated primary key strategy naming rule is `tableName_`_`strategyType`;
- `KEY_GENERATE_STRATEGY` is used to specify the primary key generation strategy, which is optional. For the primary key generation strategy, please refer to Distributed Primary Key;
- `AUDIT_STRATEGY` is used to specify the sharding audit strategy, which is optional. For the sharding audit generation strategy, please refer to Sharding Audit;
- `ifNotExists` clause is used for avoid Duplicate sharding rule error.

**Example**

1. **Standard sharding table rule**

```sql
CREATE SHARDING TABLE RULE t_order_item (
  DATANODES("ds_${0..1}.t_order_item_${0..1}"),
  DATABASE_STRATEGY(TYPE="standard",SHARDING_COLUMN=user_id,SHARDING_ALGORITHM(TYPE=NAME="inline",PROPERTIES("algorithm-expression"="ds_${user_id % 2}" ))),
  TABLE_STRATEGY(TYPE="standard",SHARDING_COLUMN=order_id,SHARDING_ALGORITHM(TYPE=NAME="inline",PROPERTIES("algorithm-expression"="t_order_item_${order_id % 2}" ))),
  KEY_GENERATE_STRATEGY(COLUMN=another_id,TYPE=NAME="snowflake"),
  AUDIT_STRATEGY (TYPE=NAME="DML_SHARDING_CONDITIONS"),ALLOW_HINT_DISABLE=true)
);```

2. **Auto sharding table rule**

```sql
CREATE SHARDING TABLE RULE t_order (
  STORAGE_UNITS(ds_0,ds_1),
  SHARDING_COLUMN=order_id,TYPE=NAME="hash_mod",PROPERTIES("sharding-count"="4" ))),
  KEY_GENERATE_STRATEGY(COLUMN=another_id,TYPE=NAME="snowflake")),
  AUDIT_STRATEGY (TYPE=NAME="DML_SHARDING_CONDITIONS"),ALLOW_HINT_DISABLE=true)
);```

9.2. ShardingSphere-Proxy
3. Create sharding rule with `ifNotExists` clause

- Standard sharding table rule

```sql
CREATE SHARDING TABLE RULE IF NOT EXISTS t_order_item (
  DATANODES("ds_${0..1}.t_order_item_${0..1}"),
  DATABASE_STRATEGY(TYPE="standard",SHARDING_COLUMN=user_id,SHARDING_ALGORITHM(TYPE=NAME="inline",PROPERTIES("algorithm-expression"="ds_${user_id % 2}" ))),
  TABLE_STRATEGY(TYPE="standard",SHARDING_COLUMN=order_id,SHARDING_ALGORITHM(TYPE=NAME="inline",PROPERTIES("algorithm-expression"="t_order_item_${order_id % 2}" ))),
  KEY_GENERATE_STRATEGY(COLUMN=another_id,TYPE=NAME="snowflake"),
  AUDIT_STRATEGY (TYPE=NAME="DML_SHARDING_CONDITIONS"),ALLOW_HINT_DISABLE=true)
```

- Auto sharding table rule

```sql
CREATE SHARDING TABLE RULE IF NOT EXISTS t_order ( 
  STORAGE_UNITS(ds_0,ds_1),
  SHARDING_COLUMN=order_id,TYPE=NAME="hash_mod",PROPERTIES("sharding-count"="4")),
  KEY_GENERATE_STRATEGY(COLUMN=another_id,TYPE=NAME="snowflake"),
  AUDIT_STRATEGY (TYPE=NAME="DML_SHARDING_CONDITIONS"),ALLOW_HINT_DISABLE=true)
```

ALTER SHARDING TABLE RULE

Description

The ALTER SHARDING TABLE RULE syntax is used to alter sharding table rule for the currently selected database.

Syntax

```
ALTER SHARDING TABLE RULE (tableDefinition | autoTableDefinition) (',',
(tableDefinition | autoTableDefinition))*
```

```
tableDefinition ::= 
   tableName '(' 'DATANODES' '(' dataNode (',', dataNode)* ')', '
   'DATABASE_ 
   STRATEGY' '(' strategyDefinition ')', '(' 'TABLE_STRATEGY' '('
   strategyDefinition ')', '(' 'KEY_GENERATE_STRATEGY' '('
   keyGenerateStrategyDefinition ')', '(' 'AUDIT_STRATEGY' '('
   auditStrategyDefinition ')')?
```

```
autoTableDefinition ::= 
   tableName '(' 'STORAGE_UNITS' '(' storageUnitName (',', storageUnitName)* ')', '
   'SHARDING_COLUMN' '=' columnName, 'algorithmDefinition', '(' 'KEY_GENERATE_ 
   STRATEGY' '(' keyGenerateStrategyDefinition ')', '(' 'AUDIT_STRATEGY' '('
   auditStrategyDefinition ')')?
```

```
strategyDefinition ::= 
   'TYPE' '=' strategyType, '(' 'SHARDING_COLUMN' | 'SHARDING_COLUMNS' ')', ' 
   columnName, 'algorithmDefinition
```

```
keyGenerateStrategyDefinition ::= 
   'KEY_GENERATE_STRATEGY' '(' 'COLUMN' '=' columnName, 'algorithmDefinition '
```

```
auditStrategyDefinition ::= 
   'AUDIT_STRATEGY' '(' algorithmDefinition, 'algorithmDefinition)* '
```

```
algorithmDefinition ::= 
   'TYPE' '(' 'NAME' '=' algorithmType, 'propertiesDefinition')?'
```

```
propertiesDefinition ::= 
   'PROPERTIES' '(' key '=' value (',', key '=' value)* '
```
Supplement

- tableDefinition is defined for standard sharding table rule; autoTableDefinition is defined for auto sharding table rule. For standard sharding rules and auto sharding rule, refer to Data Sharding;

- use standard sharding table rule:
  - DATANODES can only use resources that have been added to the current database, and can only use INLINE expressions to specify required resources;
  - DATABASE_STRATEGY, TABLE_STRATEGY are the database sharding strategy and the table sharding strategy, which are optional, and the default strategy is used when not configured;
  - The attribute TYPE in strategyDefinition is used to specify the type of Sharding Algorithm, currently only supports STANDARD, COMPLEX. Using COMPLEX requires specifying multiple sharding columns with SHARDING_COLUMNS.

- use auto sharding table rule:
  - STORAGE_UNITS can only use storage units that have been registered to the current database, and the required storage units can be specified by enumeration or INLINE expressions;
  - Only auto sharding algorithm can be used, please refer to Auto Sharding Algorithm.
• algorithmType is the sharding algorithm type, please refer to Sharding Algorithm;

• The auto-generated algorithm naming rule is tableName _ strategyType _ shardingAlgorithmType;

• The auto-generated primary key strategy naming rule is tableName _ strategyType;

• KEY_GENERATE_STRATEGY is used to specify the primary key generation strategy, which is optional. For the primary key generation strategy, please refer to Distributed Primary Key.

• AUDIT_STRATEGY is used to specify the sharding audit strategy, which is optional. For the sharding audit generation strategy, please refer to Sharding Audit.

Example

1. Standard sharding table rule

```sql
ALTER SHARDING TABLE RULE t_order_item (
  DATANODES("ds_${0..3}.t_order_item${0..3}"),
  DATABASE_STRATEGY(TYPE="standard",SHARDING_COLUMN=user_id,SHARDING_ALGORITHM(TYPE(NAME="inline"),PROPERTIES("algorithm-expression"="ds_${user_id % 4} "))),
  TABLE_STRATEGY(TYPE="standard",SHARDING_COLUMN=order_id,SHARDING_ALGORITHM(TYPE(NAME="inline"),PROPERTIES("algorithm-expression"="t_order_item_${order_id % 4}"))),
  KEY_GENERATE_STRATEGY(COLUMN=another_id,TYPE(NAME="snowflake")),
  AUDIT_STRATEGY(TYPE(NAME="dml_sharding_conditions"),ALLOW_HINT_DISABLE=true)
)
```

2. Auto sharding table rule

```sql
ALTER SHARDING TABLE RULE t_order (
  STORAGE_UNITS(ds_0,ds_1,ds_2,ds_3),
  SHARDING_COLUMN=order_id,TYPE(NAME="hash_mod"),PROPERTIES("sharding-count"="16"),
  KEY_GENERATE_STRATEGY(COLUMN=another_id,TYPE(NAME="snowflake")),
  AUDIT_STRATEGY(TYPE(NAME="dml_sharding_conditions"),ALLOW_HINT_DISABLE=true)
)
```

DROP SHARDING TABLE RULE

Description

The DROP SHARDING TABLE RULE syntax is used to drop sharding table rule for specified database.

Syntax

```
DropShardingTableRule ::= 'DROP' 'SHARDING' 'TABLE' 'RULE' ifExists? shardingRuleName (',') shardingRuleName)* (FROM databaseName)?

ifExists ::= 'IF' 'EXISTS'

shardingRuleName ::= identifier

databaseName ::= identifier
```

Supplement

- When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted;
- ifExists clause is used to avoid Sharding rule not exists error.

Example

- Drop multiple sharding table rules for specified database

```
DROP SHARDING TABLE RULE t_order, t_order_item FROM sharding_db;
```

- Drop a sharding table rule for current database

```
DROP SHARDING TABLE RULE t_order;
```

- Drop sharding table rule with ifExists clause
DROP SHARDING TABLE RULE IF EXISTS t_order;

CREATE DEFAULT SHARDING STRATEGY

Description

The CREATE DEFAULT SHARDING STRATEGY syntax is used to create a default sharding strategy

Syntax

```
CreateDefaultShardingStrategy ::= 'CREATE' 'DEFAULT' 'SHARDING' ('DATABASE' | 'TABLE') 'STRATEGY' ifNotExists? '(' shardingStrategy ')' ifNotExists ::= 'IF' 'NOT' 'EXISTS' shardingStrategy ::= 'TYPE' '=' strategyType ',' ('SHARDING_COLUMN' '=' columnName | 'SHARDING_COLUMNS' '=' columnNames) ',' 'SHARDING_ALGORITHM' '=' algorithmDefinition strategyType ::= string algorithmDefinition ::= 'TYPE' '({' 'NAME' '=' algorithmType ',' propertiesDefinition '})' columnNames ::= columnName (',' columnName)+
```

9.2. ShardingSphere-Proxy
propertiesDefinition ::= 
   'PROPERTIES' '(' key '=' value (',' key '=' value)* ')' 

key ::= 
   string 

value ::= 
   literal 

Supplement

• When using the complex sharding algorithm, multiple sharding columns need to be specified using SHARDING_COLUMNS;

• algorithmType is the sharding algorithm type. For detailed sharding algorithm type information, please refer to Sharding Algorithm;

• ifNotExists clause is used for avoid Duplicate default sharding strategy error.

Example

• create a default sharding table strategy

```sql
-- create a default sharding table strategy
CREATE DEFAULT SHARDING TABLE STRATEGY ( 
   TYPE="standard", SHARDING_COLUMN=user_id, SHARDING_ALGORITHM(TYPE(NAME="inline ", PROPERTIES("algorithm-expression"="t_order_${user_id % 2}")))
);
```

• create a default sharding table strategy with ifNotExists clause

```sql
CREATE DEFAULT SHARDING TABLE STRATEGY IF NOT EXISTS ( 
   TYPE="standard", SHARDING_COLUMN=user_id, SHARDING_ALGORITHM(TYPE(NAME="inline ", PROPERTIES("algorithm-expression"="t_order_${user_id % 2}")))
);
```

DROP DEFAULT SHARDING STRATEGY

Description

The DROP DEFAULT SHARDING STRATEGY syntax is used to drop default sharding strategy for specified database.

Syntax

```
DropDefaultShardingStrategy ::= 
   'DROP' 'DEFAULT' 'SHARDING' ('TABLE' | 'DATABASE') 'STRATEGY' ifExists? ('FROM' databaseName)?

ifExists ::= 
   'IF' 'EXISTS'

databaseName ::= 
   identifier
```
Supplement

- When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted;
- ifExists clause is used for avoid Default sharding strategy not exists error.

Example

- Drop default sharding table strategy for specified database

```sql
DROP DEFAULT SHARDING TABLE STRATEGY FROM sharding_db;
```

- Drop default sharding database strategy for current database

```sql
DROP DEFAULT SHARDING DATABASE STRATEGY;
```

- Drop default sharding table strategy with ifExists clause

```sql

DROP SHARDING KEY GENERATOR

Description

The DROP SHARDING KEY GENERATOR syntax is used to drop sharding key generator for specified database.
Syntax

DropShardingKeyGenerator ::=  
   'DROP' 'SHARDING' 'KEY' 'GENERATOR' ifExists? keyGeneratorName  
   (keyGeneratorName)* ('FROM' databaseName)?

ifExists ::=  
   'IF' 'EXISTS'

keyGeneratorName ::=  
   identifier

databaseName ::=  
   identifier

Supplement

- When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted;
- ifExists clause is used for avoid Sharding key generator not exists error.

Example

- Drop sharding key generator for specified database

DROP SHARDING KEY GENERATOR t_order_snowflake FROM sharding_db;

- Drop sharding key generator for current database

DROP SHARDING KEY GENERATOR t_order_snowflake;

- Drop sharding key generator with ifExists clause

DROP SHARDING KEY GENERATOR IF EXISTS t_order_snowflake;

DROP SHARDING ALGORITHM

Description

The DROP SHARDING ALGORITHM syntax is used to drop sharding algorithm for specified database.

Syntax

```
DropShardingAlgorithm ::=  
  'DROP' 'SHARDING' 'ALGORITHM' shardingAlgorithmName ifExists? ('FROM' 
databaseName)?

ifExists ::=  
  'IF' 'EXISTS'

shardingAlgorithmName ::=  
  identifier

databaseName ::=  
  identifier
```

Supplement

• When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted;

• ifExists clause used for avoid Sharding algorithm not exists error.

Example

• Drop sharding algorithm for specified database

```
DROP SHARDING ALGORITHM t_order_hash_mod FROM sharding_db;
```

• Drop sharding algorithm for current database

```
DROP SHARDING ALGORITHM t_order_hash_mod;
```

• Drop sharding algorithm with ifExists clause

```
DROP SHARDING ALGORITHM t_order_hash_mod;
```
DROP SHARDING ALGORITHM IF EXISTS t_order_hash_mod;

CREATE SHARDING TABLE REFERENCE RULE

Description

The CREATE SHARDING TABLE REFERENCE RULE syntax is used to create reference rule for sharding tables.

Syntax

CreateShardingTableReferenceRule ::=  
  'CREATE' 'SHARDING' 'TABLE' 'REFERENCE' 'RULE' ifNotExists?  
  referenceRelationshipDefinition (',' referenceRelationshipDefinition)*

ifNotExists ::=  
  'IF' 'NOT' 'EXISTS'

referenceRelationshipDefinition ::=  
  ruleName '(' tableName (',' tableName)* ')'  

tableName ::=  
  identifier

Supplement

- Sharding table reference rule can only be created for sharding tables;
- A sharding table can only be associated with one sharding table reference rule;
- The referenced sharding tables should be sharded in the same storage units and have the same number of sharding nodes. For example ds_${0..1}.t_order_${0..1} and ds_${0..1}.t_order_item_${0..1};
- The referenced sharding tables should use consistent sharding algorithms. For example t_order_{order_id % 2} and t_order_item_{order_item_id % 2};
ifNotExists clause used for avoid Duplicate sharding table reference rule error.

Example

1. Create a sharding table reference rule

```sql
-- Before creating a sharding table reference rule, you need to create sharding table rules t_order, t_order_item
CREATE SHARDING TABLE REFERENCE RULE ref_0 (t_order,t_order_item);
```

2. Create multiple sharding table reference rules

```sql
-- Before creating sharding table reference rules, you need to create sharding table rules t_order, t_order_item, t_product, t_product_item
CREATE SHARDING TABLE REFERENCE RULE ref_0 (t_order,t_order_item), ref_1 (t_product,t_product_item);
```

3. Create a sharding table reference rule with ifNotExists clause

```sql
CREATE SHARDING TABLE REFERENCE RULE IF NOT EXISTS ref_0 (t_order,t_order_item);
```

ALTER SHARDING TABLE REFERENCE RULE

Description

The ALTER SHARDING TABLE REFERENCE RULE syntax is used to alter sharding table reference rule.
Syntax

`AlterShardingTableReferenceRule ::= 'ALTER' 'SHARDING' 'TABLE' 'REFERENCE' 'RULE' referenceRelationshipDefinition ( ',' referenceRelationshipDefinition)*`

`referenceRelationshipDefinition ::= ruleName ('(' tableName (',' tableName)* ')')`

`tableName ::= identifier`

Supplement

- A sharding table can only be associated with one sharding table reference rule;
- The referenced sharding tables should be sharded in the same storage units and have the same number of sharding nodes. For example `ds_${0..1}.t_order_${0..1}` and `ds_${0..1}.t_order_item_${0..1}`;
- The referenced sharding tables should use consistent sharding algorithms. For example `t_order_{order_id % 2}` and `t_order_item_{order_item_id % 2}`;

Example

1. Alter a sharding table reference rule

   ```sql
   ALTER SHARDING TABLE REFERENCE RULE ref_0 (t_order,t_order_item);
   ```

2. Alter multiple sharding table reference rules

   ```sql
   ALTER SHARDING TABLE REFERENCE RULE ref_0 (t_order,t_order_item), ref_1 (t_product, t_product_item);
   ```

Broadcast Table

This chapter describes the syntax of broadcast table.

**CREATE BROADCAST TABLE RULE**

**Description**

The `CREATE BROADCAST TABLE RULE` syntax is used to create broadcast table rules for tables that need to be broadcast (broadcast tables).

**Syntax**

```
CreateBroadcastTableRule ::= 'CREATE' 'BROADCAST' 'TABLE' 'RULE' ifNotExists? tableName (',' tableName)*
ifNotExists ::= 'IF' 'NOT' 'EXISTS'
tableName ::= identifier
```

**Supplement**

- `tableName` can use an existing table or a table that will be created;
- `ifNotExists` clause is used for avoid Duplicate Broadcast rule error.
Example

Create broadcast table rule

```sql
-- Add t_province, t_city to broadcast table rules
CREATE BROADCAST TABLE RULE t_province, t_city;
```

Create broadcast table rule with ifNotExists clause

```sql
CREATE BROADCAST TABLE RULE IF NOT EXISTS t_province, t_city;
```

Reserved word

CREATE, BROADCAST, TABLE, RULE

DROP BROADCAST TABLE RULE

Description

The DROP BROADCAST TABLE RULE syntax is used to drop broadcast table rule for specified broadcast tables

Syntax

```sql
DropBroadcastTableRule ::= 
  'DROP' 'BROADCAST' 'TABLE' 'RULE' ifExists? tableName (',' tableName)*

ifExists ::= 
  'IF' 'EXISTS'

tableName ::= 
  identifier
```
Supplement

- `tableName` can use the table of existing broadcast rules;
- `ifExists` clause is used for avoid `Broadcast rule not exists` error.

Example

- Drop broadcast table rule for specified broadcast table
  ```sql
  DROP BROADCAST TABLE RULE t_province, t_city;
  ```

- Drop broadcast table rule with `ifExists` clause
  ```sql
  DROP BROADCAST TABLE RULE IF EXISTS t_province, t_city;
  ```

Single Table

This chapter describes the syntax of single table.

LOAD SINGLE TABLE

Description

The `LOAD SINGLE TABLE` syntax is used to load single table from storage unit.

Syntax

```plaintext
loadSingleTable ::= 'LOAD' 'SINGLE' 'TABLE' tableDefinition

tableDefinition ::= tableIdentifier (',' tableIdentifier)*

tableIdentifier ::= '*' '.' | '*' '.' '.' | storageUnitName '.' '*' | storageUnitName '.' '.' '.' | storageUnitName
```
```sql
'.' schemaName '.*' | storageUnitName '. ' tableName | storageUnitName '. '

storageUnitName ::= identifier

schemaName ::= identifier

tableName ::= identifier
```

**Supplement**

- support specifying schemaName in PostgreSQL and OpenGauss protocols

**Example**

- Load specified single table

```sql
LOAD SINGLE TABLE ds_0.t_single;
```

- Load all single tables in the specified storage unit

```sql
LOAD SINGLE TABLE ds_0.*;
```

- Load all single tables

```sql
LOAD SINGLE TABLE *.*;
```

**Reserved word**

LOAD, SINGLE, TABLE

UNLOAD SINGLE TABLE

Description

The UNLOAD SINGLE TABLE syntax is used to unload single table.

Syntax

unloadSingleTable ::= 'UNLOAD' 'SINGLE' 'TABLE' tableNames

tableNames ::= tableName (',' tableName)*

tableName ::= identifier

Supplement

• Unlike loading, only the table name needs to be specified when unloading a single table

Example

• Unload specified single table

UNLOAD SINGLE TABLE t_single;

• Load all single tables

UNLOAD SINGLE TABLE *;
-- or
UNLOAD ALL SINGLE TABLES;

Reserved word

UNLOAD, SINGLE, TABLE, ALL, TABLES
Related links

- Reserved word

**SET DEFAULT SINGLE TABLE STORAGE UNIT**

**Description**

The **SET DEFAULT SINGLE TABLE STORAGE UNIT** syntax is used to set default single table storage unit.

**Syntax**

```
setDefaultSingleTableStorageUnit ::= 'SET' 'DEFAULT' 'SINGLE' 'TABLE' 'STORAGE' 'UNIT' singleTableDefinition

singleTableDefinition ::= '=' (storageUnitName | 'RANDOM')

storageUnitName ::= identifier
```

**Supplement**

- STORAGE UNIT needs to use storage unit managed by RDL. The RANDOM keyword stands for random storage.

**Example**

- Set a default single table storage unit

```
SET DEFAULT SINGLE TABLE STORAGE UNIT = ds_0;
```

- Set the default single table storage unit to random storage

```
SET DEFAULT SINGLE TABLE STORAGE UNIT = RANDOM;
```
Reserved word

SET, DEFAULT, SINGLE, TABLE, STORAGE, UNIT, RANDOM

Readwrite-Splitting

This chapter describes the syntax of readwrite-splitting.

CREATE READWRITE_SPLITTING RULE

Description

The CREATE READWRITE_SPLITTING RULE syntax is used to create a read/write splitting rule.

Syntax

```
CREATEReadwriteSplittingRule ::= 'CREATE' 'READWRITE_SPLITTING' 'RULE' ifNotExists? readwriteSplittingDefinition ( ','. readwriteSplittingDefinition)*

ifNotExists ::= 'IF' 'NOT' 'EXISTS'

readwriteSplittingDefinition ::= ruleName ( dataSourceDefinition ( ','. transactionalReadQueryStrategyDefinition)? ( ','. loadBalancerDefinition)? )

dataSourceDefinition ::= 'WRITE_STORAGE_UNIT' '=>' writeStorageUnitName ', ' 'READ_STORAGE_UNITS' '(' storageUnitName ( ','. storageUnitName)* ')' transactionalReadQueryStrategyDefinition ::= 'TRANSACTIONAL_READ_QUERY_STRATEGY' '=>' transactionalReadQueryStrategyType loadBalancerDefinition ::= 'TYPE' ( 'NAME' '=>' loadBalancerType ( ','. propertiesDefinition)? )

ruleName ::= identifier

writeStorageUnitName ::= identifier
```

9.2. ShardingSphere-Proxy
identifier

storageUnitName ::= identifier

transactionalReadQueryStrategyType ::= string

loadBalancerType ::= string

propertiesDefinition ::= 'PROPERTIES' '(' key '=' value (',' key '=' value)* ')' key ::= string value ::= literal

Note

• transactionalReadQueryStrategyType specifies the routing strategy for read query within a transaction, please refer to YAML configuration;

• loadBalancerType specifies the load balancing algorithm type, please refer to Load Balance Algorithm;

• Duplicate ruleName will not be created;

• ifNotExists clause used to avoid the Duplicate readwrite_splitting rule error.

Example

Create a read/write splitting rule

CREATE READWRITE_SPLITTING RULE ms_group_0 ( WRITE_STORAGE_UNIT=write_ds, READ_STORAGE_UNITS(read_ds_0,read_ds_1), TYPE(NAME="random") );
Create read/write splitting rule with the ifNotExists clause

- read/write splitting rule

```sql
CREATE READWRITE_SPLITTING RULE IF NOT EXISTS ms_group_0 (  
    WRITE_STORAGE_UNIT=write_ds,
    READ_STORAGE_UNITS(read_ds_0,read_ds_1),
    TYPE(NAME="random")
);
```

Reserved words

CREATE, READWRITE_SPLITTING, RULE, WRITE_STORAGE_UNIT, READ_STORAGE_UNITS, TYPE, NAME, PROPERTIES, TRUE, FALSE

**ALTER READWRITE_SPLITTING RULE**

**Description**

The ALTER READWRITE_SPLITTING RULE syntax is used to alter a readwrite-splitting rule.

**Syntax**

```sql
AlterReadwriteSplittingRule ::=  
  'ALTER' 'READWRITE_SPLITTING' 'RULE' readwriteSplittingDefinition (','  
  readwriteSplittingDefinition)*

readwriteSplittingDefinition ::=  
  ruleName '(' dataSourceDefinition (',' transactionalReadQueryStrategyDefinition)?  
  (',' loadBalancerDefinition)? ')'  

dataSourceDefinition ::=  
  'WRITE_STORAGE_UNIT' '=' writeStorageUnitName ','  
  'READ_STORAGE_UNITS' '('  
  storageUnitName (',' storageUnitName)* ')'  

transactionalReadQueryStrategyDefinition ::=  
  'TRANSACTIONAL_READ_QUERY_STRATEGY' '=' transactionalReadQueryStrategyType  

loadBalancerDefinition ::=  
```
Supplement

- `transactionalReadQueryStrategyType` specifies the routing strategy for read query within a transaction, please refer to [YAML configuration](#);
- `loadBalancerType` specifies the load balancing algorithm type, please refer to [Load Balance Algorithm](#).

Example

**Alter a readwrite-splitting rule**

```
ALTER READWRITE_SPLITTING RULE ms_group_0 (  
    WRITE_STORAGE_UNIT=write_ds,  
    READ_STORAGE_UNITS(read_ds_0,read_ds_1),  
    TYPE(NAME="random")  
);
```
Reserved word

DROP READWRITE_SPLITTING RULE

Description

The **DROP READWRITE_SPLITTING RULE** syntax is used to drop readwrite-splitting rule for specified database.

Syntax

```
DropReadwriteSplittingRule ::= 'DROP' 'READWRITE_SPLITTING' 'RULE' ifExists? readwriteSplittingRuleName (',' readwriteSplittingRuleName)* ('FROM' databaseName)?
```

```
ifExists ::= 'IF' 'EXISTS'
```

```
readwriteSplittingRuleName ::= identifier
```

```
databaseName ::= identifier
```

Supplement

- When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted;
- ifExists clause is used for avoid Readwrite-splitting rule not exists error.
Example

- Drop readwrite-splitting rule for specified database
  
  `DROP READWRITE_SPLITTING RULE ms_group_1 FROM readwrite_splitting_db;`

- Drop readwrite-splitting rule for current database
  
  `DROP READWRITE_SPLITTING RULE ms_group_1;`

- Drop readwrite-splitting rule with ifExists clause
  
  `DROP READWRITE_SPLITTING RULE IF EXISTS ms_group_1;`

Reserved word

Encrypt

This chapter describes the syntax of encrypt.

**CREATE ENCRYPT RULE**

**Description**

The `CREATE ENCRYPT RULE` syntax is used to create encrypt rules.

**Syntax**

```
CreateEncryptRule ::= 'CREATE' 'ENCRYPT' 'RULE' ifNotExists? encryptDefinition (', encryptDefinition)*
ifNotExists ::= 'IF' 'NOT' 'EXISTS'
encryptDefinition ::= ruleName '(' 'COLUMNS' '(' columnDefinition (', columnDefinition)* ')' ')' columnDefinition ::=
```
'(" NAME "=' columnName '," CIPHER "=' cipherColumn{name } ," ASSISTED_QUERY "=' assistedQuery{column}{name } )? ('," LIKE_QUERY "=' likeQuery{column}{name } )? ',
encryptAlgorithmDefinition (', assistedQueryAlgorithmDefinition )? (',
likeQueryAlgorithmDefinition )? ')

encryptAlgorithmDefinition ::=  
  'ENCRYPT_ALGORITHM' '(' 'TYPE' '(' 'NAME' '=' encryptAlgorithmType (',
propertiesDefinition )? ')

assistedQueryAlgorithmDefinition ::=  
  'ASSISTED_QUERY_ALGORITHM' '(' 'TYPE' '(' 'NAME' '=' encryptAlgorithmType (',
propertiesDefinition )? ')

likeQueryAlgorithmDefinition ::=  
  'LIKE_QUERY_ALGORITHM' '(' 'TYPE' '(' 'NAME' '=' encryptAlgorithmType (',
propertiesDefinition )? ')

propertiesDefinition ::=  
  'PROPERTIES' '(' key '=' value (', key '=' value)* ')

tableName ::=  
  identifier

columnName ::=  
  identifier

cipherColumn{name } ::=  
  identifier

assistedQuery{column}{name } ::=  
  identifier

likeQuery{column}{name } ::=  
  identifier

encryptAlgorithmType ::=  
  string

key ::=  
  string

value ::=  
  literal

9.2. ShardingSphere-Proxy
Supplement

- CIPHER specifies the cipher column, ASSISTED_QUERY specifies the assisted query column, LIKE_QUERY specifies the like query column;
- encryptAlgorithmType specifies the encryption algorithm type, please refer to Encryption Algorithm;
- Duplicate ruleName will not be created;
- ifNotExists clause used for avoid Duplicate encrypt rule error.

Example

Create an encrypt rule

```sql
CREATE ENCRYPT RULE t_encrypt (  
COLUMNS(  
(NAME=user_id,CIPHER=user_cipher,ASSISTED_QUERY=assisted_query_user,LIKE_QUERY=like_query_user,ENCRYPT_ALGORITHM(TYPE(NAME='AES'),PROPERTIES('aes-key-value=')123456abc'))),ASSISTED_QUERY_ALGORITHM(TYPE(NAME='MD5'))),LIKE_QUERY_ALGORITHM(TYPE(NAME='CHAR_DIGEST_LIKE')))  
),  
t_encrypt_2 (  
COLUMNS(  
(NAME=user_id,CIPHER=user_cipher,ASSISTED_QUERY=assisted_query_user,LIKE_QUERY=like_query_user,ENCRYPT_ALGORITHM(TYPE(NAME='AES'),PROPERTIES('aes-key-value=')123456abc'))),ASSISTED_QUERY_ALGORITHM(TYPE(NAME='MD5'))),LIKE_QUERY_ALGORITHM(TYPE(NAME='CHAR_DIGEST_LIKE')))  
));
```
Create an encrypt rule with `ifNotExists` clause

```sql
CREATE ENCRYPT RULE IF NOT EXISTS t_encrypt ( 
  COLUMNS(
    (NAME=user_id,CIPHER=user_cipher,ASSISTED_QUERY=assisted_query_user,LIKE_QUERY=like_query_user,ENCRYPT_ALGORITHM(TYPE(NAME='AES'),PROPERTIES('aes-key-value'='123456abc')),ASSISTED_QUERY_ALGORITHM(TYPE(NAME='MD5')),LIKE_QUERY_ALGORITHM(TYPE(NAME='CHAR_DIGEST_LIKE'))),
    (NAME=order_id,CIPHER=order_cipher,ASSISTED_QUERY=assisted_query_order,LIKE_QUERY=like_query_order,ENCRYPT_ALGORITHM(TYPE(NAME='AES'),PROPERTIES('aes-key-value'='123456abc')),ASSISTED_QUERY_ALGORITHM(TYPE(NAME='MD5')),LIKE_QUERY_ALGORITHM(TYPE(NAME='CHAR_DIGEST_LIKE')))
  ),
  t_encrypt_2 ( 
    COLUMNS(
      (NAME=user_id,CIPHER=user_cipher,ASSISTED_QUERY=assisted_query_user,LIKE_QUERY=like_query_user,ENCRYPT_ALGORITHM(TYPE(NAME='AES'),PROPERTIES('aes-key-value'='123456abc')),ASSISTED_QUERY_ALGORITHM(TYPE(NAME='MD5')),LIKE_QUERY_ALGORITHM(TYPE(NAME='CHAR_DIGEST_LIKE'))),
      (NAME=order_id,CIPHER=order_cipher,ASSISTED_QUERY=assisted_query_order,LIKE_QUERY=like_query_order,ENCRYPT_ALGORITHM(TYPE(NAME='AES'),PROPERTIES('aes-key-value'='123456abc')),ASSISTED_QUERY_ALGORITHM(TYPE(NAME='MD5')),LIKE_QUERY_ALGORITHM(TYPE(NAME='CHAR_DIGEST_LIKE')))
    ));
```

**ALTER ENCRYPT RULE**

Description

The `ALTER ENCRYPT RULE` syntax is used to alter encryption rules.
Syntax

```
AlterEncryptRule ::= 'ALTER' 'ENCRYPT' 'RULE' encryptDefinition (',' encryptDefinition)*

encryptDefinition ::= ruleName ( '(' 'COLUMNS' '(' columnDefinition (',' columnDefinition)* ')' ')')

columnDefinition ::= '(' 'NAME' '=' columnName ', 'CIPHER' '=' cipherColumnName (',' 'ASSISTED_QUERY' '=' assistedQueryColumnName)? (',' 'LIKE_QUERY' '=' likeQueryColumnName)? ',' encryptAlgorithmDefinition (',' assistedQueryAlgorithmDefinition)? (',' likeQueryAlgorithmDefinition)? ')

encryptAlgorithmDefinition ::= 'ENCRYPT_ALGORITHM' '(' 'TYPE' '(' 'NAME' '=' encryptAlgorithmType (',' propertiesDefinition)? ')' ')

assistedQueryAlgorithmDefinition ::= 'ASSISTED_QUERY_ALGORITHM' '(' 'TYPE' '(' 'NAME' '=' encryptAlgorithmType (',' propertiesDefinition)? ')' ')

likeQueryAlgorithmDefinition ::= 'LIKE_QUERY_ALGORITHM' '(' 'TYPE' '(' 'NAME' '=' encryptAlgorithmType (',' propertiesDefinition)? ')' ')

propertiesDefinition ::= 'PROPERTIES' '(' key '=' value (',' key '=' value)* ')

tableName ::= identifier

columnName ::= identifier
cipherColumnName ::= identifier
assistedQueryColumnName ::= identifier
likeQueryColumnName ::= identifier
encryptAlgorithmType ::= string
key ::= 
```
Supplement

- CIPHER specifies the cipher column, ASSISTED_QUERY specifies the assisted query column, LIKE_QUERY specifies the like query column
- encryptAlgorithmType specifies the encryption algorithm type, please refer to Encryption Algorithm

Example

- Alter an encrypt rule

```
ALTER ENCRYPT RULE t_encrypt ( 
  COLUMNS(
    (NAME=user_id,CIPHER=user_cipher,ASSISTED_QUERY=assisted_query_user,LIKE_QUERY=like_query_user,ENCRYPT_ALGORITHM(TYPE(NAME='AES'),PROPERTIES('aes-key-value'= '123456abc'))),ASSISTED_QUERY_ALGORITHM(TYPE(NAME='MD5'))),LIKE_QUERY_ALGORITHM(TYPE(NAME='CHAR_DIGEST_LIKE'))),ASSISTED_QUERY_ALGORITHM(TYPE(NAME='MD5'))),LIKE_QUERY_ALGORITHM(TYPE(NAME='CHAR_DIGEST_LIKE'))
));
```

Reserved words

DROP ENCRYPT RULE

Description

The DROP ENCRYPT RULE syntax is used to drop an existing encryption rule.

Syntax

```
DropEncryptRule ::= 'DROP' 'ENCRYPT' 'RULE' ifExists? encryptRuleName (',', encryptRuleName)*

ifExists ::= 'IF' 'EXISTS'

encryptRuleName ::= identifier
```

Supplement

- ifExists clause is used to avoid Encrypt rule not exists error.

Example

- Drop an encrypt rule
  
  ```
  DROP ENCRYPT RULE t_encrypt, t_encrypt_2;
  ```

- Drop encrypt with ifExists clause
  
  ```
  DROP ENCRYPT RULE IF EXISTS t_encrypt, t_encrypt_2;
  ```

Mask

This chapter describes the syntax of mask.

CREATE MASK RULE

Description

The CREATE MASK RULE syntax is used to create a mask rule.

Syntax

CreateEncryptRule ::=  
   'CREATE' 'MASK' 'RULE' ifNotExists? maskRuleDefinition (', ' maskRuleDefinition)*

ifNotExists ::=  
   'IF' 'NOT' 'EXISTS'

maskRuleDefinition ::=  
   ruleName '(' 'COLUMNS' '(', columnDefinition (', ' columnDefinition)* ')') '

columnDefinition ::=  
   '(' 'NAME' '=' columnName ',' maskAlgorithmDefinition ')'

maskAlgorithmDefinition ::=  
   'TYPE' '(' 'NAME' '=' maskAlgorithmType (', ' propertiesDefinition)? ')

propertiesDefinition ::=  
   'PROPERTIES' '(' 'key' '=' value (', ' key '=' value)* ')

ruleName ::=  
   identifier

columnName ::=  
   identifier

maskAlgorithmType ::=  
   literal

key ::=  
   string

value ::=  
   literal
Note

- `maskAlgorithmType` specifies the data masking algorithm type. For more details, please refer to Data Masking Algorithm;
- `Duplicate ruleName` will not be created;
- `ifNotExists` clause is used for avoid `Duplicate mask rule` error.

Example

Create a mask rule

```sql
CREATE MASK RULE t_mask ( 
COLUMNS( 
(NAME=phone_number, TYPE(NAME='MASK_FROM_X_TO_Y', PROPERTIES("from-x"=1, "to-y"=2, "replace-char"="*"))), 
(NAME=address, TYPE(NAME='MD5')) 
));
```

Create mask rule with `ifNotExists` clause

```sql
CREATE MASK RULE IF NOT EXISTS t_mask ( 
COLUMNS( 
(NAME=phone_number, TYPE(NAME='MASK_FROM_X_TO_Y', PROPERTIES("from-x"=1, "to-y"=2, "replace-char"="*"))), 
(NAME=address, TYPE(NAME='MD5')) 
));
```

Reserved words

ALTER MASK RULE

Description

The ALTER MASK RULE syntax is used to create a mask rule.

Syntax

```
AlterEncryptRule ::= 'ALTER' 'MASK' 'RULE' maskRuleDefinition (',' maskRuleDefinition)*

maskRuleDefinition ::= ruleName '(' 'COLUMNS' '(' columnDefinition (',' columnDefinition)* ')' ')'

columnDefinition ::= '(' 'NAME' '=' columnName ',' maskAlgorithmDefinition ')

maskAlgorithmDefinition ::= 'TYPE' '(' 'NAME' '=' maskAlgorithmType (',' propertiesDefinition)? ')

propertiesDefinition ::= 'PROPERTIES' '(' key '=' value (',' key '=' value)* ')

ruleName ::= identifier

columnName ::= identifier

maskAlgorithmType ::= literal

def
```

Supplement

- `maskAlgorithmType` specifies the data masking algorithm type, please refer to Data Masking Algorithm.

Example

Alter a mask rule

```sql
ALTER MASK RULE t_mask (
  COLUMNS(
    (NAME=phone_number, TYPE(NAME='MASK_FROM_X_TO_Y', PROPERTIES("from-x"=1, "to-y"=2, "replace-char"="*")),
    (NAME=address, TYPE(NAME='MD5'))
  ));
```

Reserved words

DROP MASK RULE

Description

The DROP MASK RULE syntax is used to drop existing mask rule.

Syntax

```
DropEncryptRule ::= 'DROP' 'MASK' 'RULE' ifExists? maskRuleName (', maskRuleName)*

ifExists ::= 'IF' 'EXISTS'

maskRuleName ::= identifier
```
Supplement

- ifExists clause used for avoid Mask rule not exists error.

Example

- Drop mask rule

```sql
DROP MASK RULE t_mask, t_mask_1;
```

- Drop mask rule with ifExists clause

```sql
DROP MASK RULE IF EXISTS t_mask, t_mask_1;
```

Shadow

This chapter describes the syntax of shadow.

CREATE SHADOW RULE

Description

The CREATE SHADOW RULE syntax is used to create a shadow rule.

Syntax

```sql
CreateShadowRule ::= 'CREATE' 'SHADOW' 'RULE' ifNotExists? shadowRuleDefinition (','
shadowRuleDefinition)*

ifNotExists ::= 'IF' 'NOT' 'EXISTS'

shadowRuleDefinition ::= ruleName '(' storageUnitMapping shadowTableRule (',' shadowTableRule)* ')
```
storageUnitMapping ::= 'SOURCE' '=' storageUnitName ', ' 'SHADOW' '=' storageUnitName

shadowTableRule ::= tableName '(' shadowAlgorithm ')' 

shadowAlgorithm ::= 'TYPE' '(' 'NAME' '=' shadowAlgorithmType ', ' propertiesDefinition ')' 

ruleName ::= identifier 

storageUnitName ::= identifier 

tableName ::= identifier 

algorithmName ::= identifier 

shadowAlgorithmType ::= string 

propertiesDefinition ::= 'PROPERTIES' '(' key '=' value (', ' key '=' value)* ')' 

key ::= string 

value ::= literal 

Supplement

• Duplicate ruleName cannot be created;
• storageUnitMapping specifies the mapping relationship between the source database and the shadow library. You need to use the storage unit managed by RDL, please refer to STORAGE UNIT;
• shadowAlgorithm can act on multiple shadowTableRule at the same time;
• If algorithmName is not specified, it will be automatically generated according to ruleName, tableName and shadowAlgorithmType;
• shadowAlgorithmType currently supports VALUE_MATCH, REGEX_MATCH and SQL_HINT;
ifNotExists clause is used for avoid Duplicate shadow rule error.

Example

- Create a shadow rule

```sql
CREATE SHADOW RULE shadow_rule(
    SOURCE=demo_ds,
    SHADOW=demo_ds_shadow,
    t_order(TYPE(NAME="SQL_HINT")),
    t_order_item(TYPE(NAME="VALUE_MATCH", PROPERTIES("operation"="insert","column"="user_id", "value"='1'))))
);
```

- Create a shadow rule with ifNotExists clause

```sql
CREATE SHADOW RULE IF NOT EXISTS shadow_rule(
    SOURCE=demo_ds,
    SHADOW=demo_ds_shadow,
    t_order(TYPE(NAME="SQL_HINT")),
    t_order_item(TYPE(NAME="VALUE_MATCH", PROPERTIES("operation"="insert","column"="user_id", "value"='1'))))
);
```

ALTER SHADOW RULE

Description

The ALTER SHADOW RULE syntax is used to alter shadow rule.
Syntax

AlterShadowRule ::= 
   'ALTER' 'SHADOW' 'RULE' shadowRuleDefinition (',' shadowRuleDefinition)*

shadowRuleDefinition ::= 
   ruleName ' '::' storageUnitMapping shadowTableRule (',' shadowTableRule)*'')'

storageUnitMapping ::= 
   'SOURCE' ':' storageUnitName ',' 'SHADOW' ':' storageUnitName

shadowTableRule ::= 
   tableName '(' shadowAlgorithm ')

shadowAlgorithm ::= 
   'TYPE' '(' 'NAME' ':' shadowAlgorithmType ',' propertiesDefinition ')

ruleName ::= 
   identifier

storageUnitName ::= 
   identifier

tableName ::= 
   identifier

algorithmName ::= 
   identifier

shadowAlgorithmType ::= 
   string

propertiesDefinition ::= 
   'PROPERTIES' '(' 'key' ':' value (',' 'key' ':' value)* ')

key ::= 
   string

value ::= 
   literal
Supplement

• storageUnitMapping specifies the mapping relationship between the source database and the shadow library. You need to use the storage unit managed by RDL, please refer to STORAGE UNIT;

• shadowAlgorithm can act on multiple shadowTableRule at the same time;

• If algorithmName is not specified, it will be automatically generated according to ruleName, tableName and shadowAlgorithmType;

• shadowAlgorithmType currently supports VALUE_MATCH, REGEX_MATCH and SQL_HINT.

Example

• Create a shadow rule

```
ALTER SHADOW RULE shadow_rule(
  SOURCE=demo_ds,
  SHADOW=demo_ds_shadow,
  t_order(TYPE(NAME="SQL_HINT")),
  t_order_item(TYPE(NAME="VALUE_MATCH", PROPERTIES("operation"="insert","column"="user_id", "value"='1'))))
);
```

DROP SHADOW RULE

Description

The DROP SHADOW RULE syntax is used to drop shadow rule for specified database
Syntax

DropShadowRule ::= ’DROP' 'SHADOW' 'RULE' ifExists? shadowRuleName (‘FROM' databaseName)?

ifExists ::= ’IF' 'EXISTS'

shadowRuleName ::= identifier

databaseName ::= identifier

Supplement

• When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted;

• ifExists clause is used for avoid Shadow rule not exists error.

Example

• Drop shadow rule for specified database

DROP SHADOW RULE shadow_rule FROM shadow_db;

• Drop shadow rule for current database

DROP SHADOW RULE shadow_rule;

• Drop shadow rule with ifExists clause

DROP SHADOW RULE IF EXISTS shadow_rule;

**CREATE DEFAULT SHADOW ALGORITHM**

**Description**

The `CREATE DEFAULT SHADOW ALGORITHM` syntax is used to create a default shadow algorithm.

**Syntax**

```
CreateDefaultShadowAlgorithm ::= 'CREATE' 'DEFAULT' 'SHADOW' 'ALGORITHM' ifNotExists? shadowAlgorithm

ifNotExists ::= 'IF' 'NOT' 'EXISTS'

shadowAlgorithm ::= 'TYPE' '(' 'NAME' '=' shadowAlgorithmType ',' propertiesDefinition ')'

shadowAlgorithmType ::= string

propertiesDefinition ::= 'PROPERTIES' '(' key '=' value (',' key '=' value)* ')'

key ::= string

value ::= literal
```

**Supplement**

- `shadowAlgorithmType` currently supports `VALUE_MATCH`, `REGEX_MATCH` and `SQL_HINT`;
- `ifNotExists` clause is used for avoid Duplicate default shadow algorithm error.
Example

- Create default shadow algorithm

```sql
CREATE DEFAULT SHADOW ALGORITHM TYPE(NAME="SQL_HINT");
```

- Create default shadow algorithm with `ifNotExists` clause

```sql
CREATE DEFAULT SHADOW ALGORITHM IF NOT EXISTS TYPE(NAME="SQL_HINT");
```

ALTER DEFAULT SHADOW ALGORITHM

Description

The `ALTER DEFAULT SHADOW ALGORITHM` syntax is used to alter a default shadow algorithm.

Syntax

```sql
AlterDefaultShadowAlgorithm ::= 
  'ALTER' 'DEFAULT' 'SHADOW' 'ALGORITHM' shadowAlgorithm

shadowAlgorithm ::= 
  'TYPE' '(' 'NAME' '=' shadowAlgorithmType ',' propertiesDefinition ')' 

shadowAlgorithmType ::= 
  string 

propertiesDefinition ::= 
  'PROPERTIES' '(' 'key' '=' value (',' 'key' '=' value)* ')' 

key ::= 
  string 

value ::= 
  literal
```
Supplement

- shadowAlgorithmType currently supports VALUE_MATCH, REGEX_MATCH and SQL_HINT.

Example

- Alter default shadow algorithm

```
ALTER DEFAULT SHADOW ALGORITHM TYPE(NAME="SQL_HINT");
```

DROP DEFAULT SHADOW ALGORITHM

Description

The DROP DEFAULT SHADOW ALGORITHM syntax is used to drop default shadow algorithm for specified database

Syntax

```
DropDefaultShadowAlgorithm ::= 
  'DROP' 'DEFAULT' 'SHADOW' 'ALGORITHM' ifExists? ('FROM' databaseName)?
ifExists ::= 
  'IF' 'EXISTS'
databaseName ::= 
  identifier
```
Supplement

- When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted;
- ifExists clause used for avoid Default shadow algorithm not exists error.

Example

- Drop default shadow algorithm for specified database

```sql
DROP DEFAULT SHADOW ALGORITHM FROM shadow_db;
```

- Drop default shadow algorithm for current database

```sql
DROP DEFAULT SHADOW ALGORITHM;
```

- Drop default shadow algorithm with ifExists clause

```sql
DROP DEFAULT SHADOW ALGORITHM IF EXISTS;
```

DROP SHADOW ALGORITHM

Description

The DROP SHADOW ALGORITHM syntax is used to drop shadow algorithm for specified database

Syntax

```
DropShadowAlgorithm ::= 'DROP' 'SHADOW' 'ALGORITHM' ifExists? shadowAlgorithmName (',' shadowAlgorithmName)* ('FROM' databaseName)?

ifExists ::= 'IF' 'EXISTS'
```
shadowAlgorithmName ::= identifier

databaseName ::= identifier

**Supplement**

- When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted;
- `ifExists` clause is used for avoid shadow algorithm not exists error.

**Example**

- Drop mutiple shadow algorithm for specified database

```sql
DROP SHADOW ALGORITHM shadow_rule_t_order_sql_hint_0, shadow_rule_t_order_item_sql_hint_0 FROM shadow_db;
```

- Drop single shadow algorithm for current database

```sql
DROP SHADOW ALGORITHM shadow_rule_t_order_sql_hint_0;
```

- Drop shadow algorithm with `ifExists` clause

```sql
DROP SHADOW ALGORITHM IF EXISTS shadow_rule_t_order_sql_hint_0;
```

**RQL Syntax**

RQL (Resource & Rule Query Language) responsible for resources/rules query.
Storage Unit Query

This chapter describes the syntax of storage unit query.

SHOW STORAGE UNITS

Description

The SHOW STORAGE UNITS syntax is used to query the storage units that have been added to the specified database.

Syntax

```
ShowStorageUnit ::= 'SHOW' 'STORAGE' 'UNITS' ('WHERE' 'USAGE_COUNT' '=' usageCount)? ('FROM' databaseName)?
```

usageCount ::= int

databaseName ::= identifier

Supplement

- When databaseName is not specified, the default is the currently used DATABASE; if DATABASE is not used, it will prompt No database selected.

Return Value Description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Storage unit name</td>
</tr>
<tr>
<td>type</td>
<td>Storage unit type</td>
</tr>
<tr>
<td>host</td>
<td>Storage unit host</td>
</tr>
<tr>
<td>port</td>
<td>Storage unit port</td>
</tr>
<tr>
<td>db</td>
<td>Database name</td>
</tr>
<tr>
<td>attribute</td>
<td>Storage unit attribute</td>
</tr>
</tbody>
</table>

Example

- Query unused storage units for the specified database
SHOW STORAGE UNITS WHERE USAGE_COUNT = 0 FROM sharding_db;

mysql> SHOW STORAGE UNITS WHERE USAGE_COUNT = 0 FROM sharding_db;

Rule Query

This chapter describes the syntax of rule query.

Sharding

This chapter describes the syntax of sharding.

SHOW SHARDING TABLE RULE

Description

The SHOW SHARDING TABLE RULE syntax is used to query the sharding table rule in the specified database.

Syntax

```
ShowShardingTableRule ::= 
  'SHOW' 'SHARDING' 'TABLE' ('RULE' tableName | 'RULES') ('FROM' databaseName)?

tableName ::= 
  identifier

databaseName ::= 
  identifier
```
Supplement

- When `databaseName` is not specified, the default is the currently used `DATABASE`. If `DATABASE` is not used, `No database selected` will be prompted.

### Return value description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>Logical table name</td>
</tr>
<tr>
<td>actual_data_nodes</td>
<td>Actual data node</td>
</tr>
<tr>
<td>actual_data_sources</td>
<td>Actual data source (Displayed when creating rules by RDL)</td>
</tr>
<tr>
<td>database_strategy_type</td>
<td>Database sharding strategy type</td>
</tr>
<tr>
<td>database_sharding_column</td>
<td>Database sharding column</td>
</tr>
<tr>
<td>database_sharding_algorithm_type</td>
<td>Database sharding algorithm type</td>
</tr>
<tr>
<td>database_sharding_algorithm_props</td>
<td>Database sharding algorithm properties</td>
</tr>
<tr>
<td>table_strategy_type</td>
<td>Table sharding strategy type</td>
</tr>
<tr>
<td>table_sharding_column</td>
<td>Table sharding column</td>
</tr>
<tr>
<td>table_sharding_algorithm_type</td>
<td>Table sharding algorithm type</td>
</tr>
<tr>
<td>table_sharding_algorithm_props</td>
<td>Table sharding algorithm properties</td>
</tr>
<tr>
<td>key_generate_column</td>
<td>Sharding key generator column</td>
</tr>
<tr>
<td>key_generator_type</td>
<td>Sharding key generator type</td>
</tr>
<tr>
<td>key_generator_props</td>
<td>Sharding key generator properties</td>
</tr>
</tbody>
</table>

### Example

- Query the sharding table rules of the specified logical database

```sql
SHOW SHARDING TABLE RULES FROM sharding_db;
```

<table>
<thead>
<tr>
<th>table</th>
<th>actual_data_nodes</th>
<th>actual_data_sources</th>
<th>database_strategy_type</th>
<th>database_sharding_column</th>
<th>database_sharding_algorithm_type</th>
<th>database_sharding_algorithm_props</th>
<th>table_strategy_type</th>
<th>table_sharding_column</th>
<th>table_sharding_algorithm_type</th>
<th>table_sharding_algorithm_props</th>
<th>key_generate_column</th>
<th>key_generator_type</th>
<th>key_generator_props</th>
</tr>
</thead>
<tbody>
<tr>
<td>t_order</td>
<td></td>
<td>ds_0,ds_1</td>
<td>mod</td>
<td>order_id</td>
<td>mod</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>sharding-count=4</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>t_order_item</td>
<td></td>
<td>ds_0,ds_1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| mod | order_id | mod
| sharding-count=4 | | | |

2 rows in set (0.12 sec)

- Query the sharding table rules of the current logic database

```sql
SHOW SHARDING TABLE RULES;
```

---

<table>
<thead>
<tr>
<th>table</th>
<th>actual_data_nodes</th>
<th>actual_data_sources</th>
<th>database_strategy_type</th>
<th>database_sharding_column</th>
<th>database_sharding_algorithm_type</th>
<th>database_sharding_algorithm_props</th>
<th>table_strategy_type</th>
<th>table_sharding_column</th>
<th>table_sharding_algorithm_type</th>
<th>table_sharding_algorithm_props</th>
<th>key_generate_column</th>
<th>key_generator_type</th>
<th>key_generator_props</th>
</tr>
</thead>
<tbody>
<tr>
<td>t_order</td>
<td></td>
<td>ds_0,ds_1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| mod | order_id | mod
| t_order_item | | ds_0,ds_1 | |
| mod | order_id | mod
| t_order_item | | ds_0,ds_1 | |
| mod | order_id | mod
| sharding-count=4 | | | |

9.2. ShardingSphere-Proxy
• Query the specified sharding table rule

```
SHOW SHARDING TABLE RULE t_order;
```

<table>
<thead>
<tr>
<th>table</th>
<th>actual_data_nodes</th>
<th>actual_data_sources</th>
<th>database_strategy_type</th>
<th>database_sharding_column</th>
<th>database_sharding_algorithm_type</th>
<th>database_sharding_algorithm_props</th>
<th>table_strategy_type</th>
<th>table_sharding_column</th>
<th>table_sharding_algorithm_type</th>
<th>table_sharding_algorithm_props</th>
<th>key_generate_column</th>
<th>key_generator_type</th>
<th>key_generator_props</th>
</tr>
</thead>
<tbody>
<tr>
<td>t_order</td>
<td></td>
<td>ds_0,ds_1</td>
<td></td>
<td></td>
<td>mod</td>
<td>order_id</td>
<td>mod</td>
<td></td>
<td>sharding-count=4</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>

**SHOW SHARDING ALGORITHMS**

**Description**

The `SHOW SHARDING ALGORITHMS` syntax is used to query the sharding algorithms in the specified database.

**Syntax**

```
ShowShardingAlgorithms ::= 
    'SHOW' 'SHARDING' 'ALGORITHMS' ('FROM' databaseName)?
```

`databaseName ::= identifier`

**Supplement**

- When `databaseName` is not specified, the default is the currently used `DATABASE`. If `DATABASE` is not used, `No database selected` will be prompted.

**Return value description**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Sharding algorithm name</td>
</tr>
<tr>
<td>type</td>
<td>Sharding algorithm type</td>
</tr>
<tr>
<td>props</td>
<td>Sharding algorithm properties</td>
</tr>
</tbody>
</table>

**Example**

- Query the sharding table algorithms of the specified logical database

```
SHOW SHARDING ALGORITHMS FROM sharding_db;
```

```
mysql> SHOW SHARDING ALGORITHMS FROM sharding_db;
+-------------------------+--------+-----------------------------------------------+
| name | type | props |
|------+------|-------|
```

**9.2. ShardingSphere-Proxy**
Query the sharding table algorithms of the current logical database

SHOW SHARDING ALGORITHMS;

mysql> SHOW SHARDING ALGORITHMS;

<table>
<thead>
<tr>
<th>name</th>
<th>type</th>
<th>props</th>
</tr>
</thead>
<tbody>
<tr>
<td>t_order_inline</td>
<td>INLINE</td>
<td>algorithm-expression=t_order_${order_id % 2}</td>
</tr>
<tr>
<td>t_order_item_inline</td>
<td>INLINE</td>
<td>algorithm-expression=t_order_item_${order_id % 2}</td>
</tr>

SHOW UNUSED SHARDING ALGORITHMS

Description

The SHOW UNUSED SHARDING ALGORITHMS syntax is used to query the unused sharding algorithms in the specified database.
Syntax

```
ShowShardingAlgorithms ::= 'SHOW' 'UNUSED' 'SHARDING' 'ALGORITHMS' ( 'FROM' databaseName )?
```

databaseName ::= identifier

Supplement

- When `databaseName` is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted.

Return value description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Sharding algorithm name</td>
</tr>
<tr>
<td>type</td>
<td>Sharding algorithm type</td>
</tr>
<tr>
<td>props</td>
<td>Sharding algorithm properties</td>
</tr>
</tbody>
</table>

Example

- Query the unused sharding table algorithms of the specified logical database

```
SHOW UNUSED SHARDING ALGORITHMS;
```

```
mysql> SHOW UNUSED SHARDING ALGORITHMS;
+---------------+--------+-----------------------------------------------------+
| name | type | props |
| t1_inline | INLINE | algorithm-expression=t_order_${order_id % 2} |
+---------------+--------+-----------------------------------------------------+

SHOW DEFAULT SHARDING STRATEGY

Description

The SHOW DEFAULT SHARDING STRATEGY syntax is used to query default sharding strategy in specified database.

Syntax

```
ShowDefaultShardingStrategy ::= 'SHOW' 'DEFAULT' 'SHARDING' 'STRATEGY' ('FROM' databaseName)?
```

databaseName ::= identifier

Supplement

- When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted.

Return value description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Sharding strategy scope</td>
</tr>
<tr>
<td>type</td>
<td>Sharding strategy type</td>

Example

- Query sharding table nodes for specified table in the specified logical database

```sql
SHOW SHARDING TABLE NODES t_order_item FROM sharding_db;
```

```
+--------+-------------------------------------------------------------------+
| name   | nodes                                                             |
|--------+-------------------------------------------------------------------|
+--------+-------------------------------------------------------------------|
| t_order_item | resource_0.t_order_item_0, resource_0.t_order_item_1, resource_1. t_order_item_0, resource_1.t_order_item_1 |
+--------+-------------------------------------------------------------------|
1 row in set (0.00 sec)
```

- Query sharding table nodes for specified table in the current logical database

```sql
SHOW SHARDING TABLE NODES t_order_item;
```

```
+--------+-------------------------------------------------------------------+
| name   | nodes                                                             |
|--------+-------------------------------------------------------------------|
+--------+-------------------------------------------------------------------|
| t_order_item | resource_0.t_order_item_0, resource_0.t_order_item_1, resource_1. t_order_item_0, resource_1.t_order_item_1 |
+--------+-------------------------------------------------------------------|
1 row in set (0.00 sec)
```

- Query sharding table nodes for all tables in the specified logical database

```sql
SHOW SHARDING TABLE NODES FROM sharding_db;
```

```
+--------+-------------------------------------------------------------------+
| name   | nodes                                                             |
|--------+-------------------------------------------------------------------|
+--------+-------------------------------------------------------------------|
| t_order_item | resource_0.t_order_item_0, resource_0.t_order_item_1, resource_1. t_order_item_0, resource_1.t_order_item_1 |
+--------+-------------------------------------------------------------------|
```
• Query sharding table nodes for all tables in the current logical database

SHOW SHARDING TABLE NODES;

```
mysql> SHOW SHARDING TABLE NODES;
+------------+-------------------------------------------------------------------+-
| name       | nodes                                                             |
+------------+-------------------------------------------------------------------+-
| t_order_item | resource_0.t_order_item_0, resource_0.t_order_item_1, resource_1. |
|            | t_order_item_0, resource_1.t_order_item_0, resource_1.t_order_item_1 |
+------------+-------------------------------------------------------------------+-
1 row in set (0.00 sec)
```

SHOW SHARDING TABLE NODES

Description

SHOW SHARDING TABLE RULES USED ALGORITHM syntax is used to query sharding rules used specified sharding algorithm in specified logical database
Syntax

ShowShardingTableRulesUsedAlgorithm ::= 
'SHOW' 'SHARDING' 'TABLE' 'RULES' 'USED' 'ALGORITHM' algorithmName ('FROM' 
databaseName)?

algorithmName ::= 
identifier

databaseName ::= 
identifier

Supplement

• When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted.

Return value description

<table>
<thead>
<tr>
<th>Columns</th>
<th>Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>Sharding rule type</td>
</tr>
<tr>
<td>name</td>
<td>Sharding rule name</td>
</tr>
</tbody>
</table>

Example

• Query sharding table rules for the specified sharding algorithm in specified logical database

SHOW SHARDING TABLE RULES USED ALGORITHM table_inline FROM sharding_db;

mysql> SHOW SHARDING TABLE RULES USED ALGORITHM table_inline FROM sharding_db;
+------------------+
| type  | name     |
+------------------+
| table | t_order_item |
+------------------+
1 row in set (0.00 sec)

• Query sharding table rules for specified sharding algorithm in the current logical database

COUNT SHARDING RULE

Description

The COUNT SHARDING RULE syntax is used to query the number of sharding rules for specified database.

Syntax

```
CountShardingRule ::= 'COUNT' 'SHARDING' 'RULE' ('FROM' databaseName)?
```

databaseName ::= identifier

Supplement

• When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted.

Return value description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_name</td>
<td>rule type</td>
</tr>
<tr>
<td>database</td>
<td>the database to which the rule belongs</td>
</tr>
<tr>
<td>count</td>
<td>the number of the rule</td>
</tr>
</tbody>
</table>

Example

• Query the number of sharding rules for specified database.

```
COUNT SHARDING RULE FROM sharding_db;
```

```
mysql> COUNT SHARDING RULE FROM sharding_db;
+-----------+--------+-------+
<table>
<thead>
<tr>
<th>rule_name</th>
<th>database</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>sharding_table</td>
<td>sharding_db</td>
<td>2</td>
</tr>
<tr>
<td>sharding_table_reference</td>
<td>sharding_db</td>
<td>2</td>
</tr>
</tbody>
</table>
+-----------+---------+-------+
2 rows in set (0.00 sec)
```

• Query the number of sharding rules for current database.

9.2. ShardingSphere-Proxy
COUNT SHARDING RULE;

mysql> COUNT SHARDING RULE;
+--------------------------+----------------+-------+

Broadcast Table

This chapter describes the syntax of broadcast table.

SHOW BROADCAST TABLE RULE

Description

The SHOW BROADCAST TABLE RULE syntax is used to broadcast tables for specified database.

Syntax

ShowBroadcastTableRule ::= 
  'SHOW' 'BROADCAST' 'TABLE' 'RULES' ('FROM' databaseName)?

databaseName ::= 
  identifier

9.2. ShardingSphere-Proxy 265
Supplement

- When `databaseName` is not specified, the default is the currently used `DATABASE`. If `DATABASE` is not used, `No database selected` will be prompted.

Return value description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>broadcast_table</td>
<td>Broadcast table name</td>
</tr>
</tbody>
</table>

Example

- Query broadcast tables for specified database.

```
SHOW BROADCAST TABLE RULES FROM sharding_db;
```

```
mysql> SHOW BROADCAST TABLE RULES FROM sharding_db;
+-----------------+
| broadcast_table |
+-----------------+
| t_a             |
| t_b             |
| t_c             |
+-----------------+
3 rows in set (0.00 sec)
```

- Query broadcast table for current database.

```
SHOW BROADCAST TABLE RULES;
```

```
mysql> SHOW BROADCAST TABLE RULES;
+-----------------+
| broadcast_table |
+-----------------+
| t_a             |
| t_b             |

Single Table

This chapter describes the syntax of single table.
SHOW SINGLE TABLE

Description

The SHOW SINGLE TABLE syntax is used to query single tables for specified database.

Syntax

```
ShowSingleTable ::= 'SHOW' 'SINGLE' ('TABLES' ('LIKES' likeLiteral)? | 'TABLE' tableName) ('FROM' databaseName)?
```

tableName ::= identifier
databaseName ::= identifier

Supplement

- When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted.

Return value description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_name</td>
<td>Single table name</td>
</tr>
<tr>
<td>storage_unit_name</td>
<td>The storage unit name where the single table is located</td>
</tr>
</tbody>
</table>

Example

- Query specified single table for specified database.

```
SHOW SINGLE TABLE t_user FROM sharding_db;
```

```
mysql> SHOW SINGLE TABLE t_user FROM sharding_db;
+-----------------+-------------------+
| table_name      | storage_unit_name |
+-----------------+-------------------+
| t_user          | ds_0              |
+-----------------+-------------------+
1 row in set (0.00 sec)
```
• Query specified single table for current database.

```sql
SHOW SINGLE TABLE t_user;
```

```
mysql> SHOW SINGLE TABLE t_user;
+-----------------------------+-------------------+
| table_name | storage_unit_name |
+-------------+-------------------+
| t_user     | ds_0              |
+-------------+-------------------+
1 row in set (0.00 sec)
```

• Query single tables for specified database.

```sql
SHOW SINGLE TABLES FROM sharding_db;
```

```
mysql> SHOW SINGLE TABLES FROM sharding_db;
+-----------------------------+-------------------+
| table_name | storage_unit_name |
+-------------+-------------------+
| t_user     | ds_0              |
+-------------+-------------------+
1 row in set (0.00 sec)
```

• Query single tables for current database.

```sql
SHOW SINGLE TABLES;
```

```
mysql> SHOW SINGLE TABLES;
+-----------------------------+-------------------+
| table_name | storage_unit_name |
+-------------+-------------------+
| t_user     | ds_0              |
+-------------+-------------------+
1 row in set (0.00 sec)
```

• Query the single tables whose table name end with order_5 for the specified logic database.

```sql
SHOW SINGLE TABLES LIKE '%order_5' FROM sharding_db;
```

```
mysql> SHOW SINGLE TABLES LIKE '%order_5' FROM sharding_db;
+-----------------------------+-------------------+
| table_name | storage_unit_name |
+-------------+-------------------+
| t_order_5  | ds_1              |
+-------------+-------------------+
1 row in set (0.11 sec)
```

• Query the single tables whose table name end with order_5 for the current logic database
SHOW SINGLE TABLES LIKE '%order_5';

mysql> SHOW SINGLE TABLES LIKE '%order_5';
+------------+-------------------+
<table>
<thead>
<tr>
<th>table_name</th>
<th>storage_unit_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>t_order_5</td>
<td>ds_1</td>
</tr>

SHOW DEFAULT SINGLE TABLE STORAGE UNIT

Description

The SHOW DEFAULT SINGLE TABLE STORAGE UNIT syntax is used to query storage units for specified database.

Syntax

```
SHOW DEFAULT SINGLE TABLE STORAGE UNIT :=
'SHOW' 'DEFAULT' 'SINGLE' 'TABLE' 'STORAGE' 'UNIT' ('FROM' databaseName)?
```

databaseName ::= identifier

Supplement

- When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted.
Return Value Description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>storage_unit_name</td>
<td>Storage unit name</td>
</tr>
</tbody>
</table>

Example

- Query storage units for specified database.

```sql
SHOW DEFAULT SINGLE TABLE STORAGE UNIT
```

```sql
sql> SHOW DEFAULT SINGLE TABLE STORAGE UNIT;

Encrypt

This chapter describes the syntax of encrypt.

SHOW ENCRYPT RULES

Description

The SHOW ENCRYPT RULES syntax is used to query encryption rules for a specified database.

Syntax

```
SHOW Encrypt ::= 
    "SHOW" "ENCRYPT" ("RULES" | "TABLE" "RULE" ruleName) ("FROM" databaseName)?

ruleName ::= 
    identifier

databaseName ::= 
    identifier
```

Note

- When databaseName is not specified, then DATABASE is currently used as the default name. If DATABASE is not used, you will receive a No database selected prompt.
Return value description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>Logical table name</td>
</tr>
<tr>
<td>logic_column</td>
<td>Logical column name</td>
</tr>
<tr>
<td>cipher_column</td>
<td>Ciphertext column name</td>
</tr>
<tr>
<td>assisted_query_column</td>
<td>Assisted query column name</td>
</tr>
<tr>
<td>like_query_column</td>
<td>Like query column name</td>
</tr>
<tr>
<td>encryptor_type</td>
<td>Encryption algorithm type</td>
</tr>
<tr>
<td>encryptor_props</td>
<td>Encryption algorithm parameter</td>
</tr>
<tr>
<td>assisted_query_type</td>
<td>Assisted query algorithm type</td>
</tr>
<tr>
<td>assisted_query_props</td>
<td>Assisted query algorithm parameter</td>
</tr>
<tr>
<td>like_query_type</td>
<td>Like query algorithm type</td>
</tr>
<tr>
<td>like_query_props</td>
<td>Like query algorithm parameter</td>
</tr>
</tbody>
</table>

Example

- Query encrypt rules for specified database.

```sql
SHOW ENCRYPT RULES FROM encrypt_db;
```

```sql
mysql> SHOW ENCRYPT RULES FROM encrypt_db;
+---------------+----------------++----------------------------++-----------------------+---------------+----------------++-----------------+-----------------++----------------++---------------+----------------+

COUNT ENCRYPT RULE

Description
The COUNT ENCRYPT RULE syntax is used to query the number of encrypt rules for specified database.

Syntax
CountEncryptRule ::= 'COUNT' 'ENCRYPT' 'RULE' ('FROM' databaseName)?
databaseName ::= identifier
Supplement

• When `databaseName` is not specified, the default is the currently used `DATABASE`. If `DATABASE` is not used, `No database selected` will be prompted.

**Return value description**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_name</td>
<td>rule type</td>
</tr>
<tr>
<td>database</td>
<td>the database to which the rule belongs</td>
</tr>
<tr>
<td>count</td>
<td>the number of the rule</td>
</tr>
</tbody>
</table>

**Example**

• Query the number of encrypt rules for specified database.

```
COUNT ENCRYPT RULE FROM encrypt_db;
```

```
mysql> COUNT ENCRYPT RULE FROM encrypt_db;
+-------------------+-----------+-------+
<table>
<thead>
<tr>
<th>rule_name</th>
<th>database</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>encrypt</td>
<td>encrypt_db</td>
<td>2</td>
</tr>
</tbody>
</table>

Mask

This chapter describes the syntax of mask.

SHOW MASK RULES

Description

The SHOW MASK RULES syntax is used to query mask rules for specified database.

Syntax

ShowMaskRule ::= 'SHOW' 'MASK' ('RULES' | 'RULE' ruleName) ('FROM' databaseName)?

ruleName ::= identifier

databaseName ::= identifier

Supplement

- When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted.

Return value description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>Table name</td>
</tr>
<tr>
<td>column</td>
<td>Column name</td>
</tr>
<tr>
<td>algorithm_type</td>
<td>Mask algorithm type</td>
</tr>
<tr>
<td>algorithm_props</td>
<td>Mask algorithm properties</td>
</tr>
</tbody>
</table>
### Example

- Query mask rules for specified database

```sql
SHOW MASK RULES FROM mask_db;
```

```sql
mysql> SHOW MASK RULES FROM mask_db;
```

<table>
<thead>
<tr>

**Syntax**

```
AlterTransactionRule ::= 'ALTER' 'TRANSACTION' 'RULE' '('
  'DEFAULT' 'etermine' defaultTransactionType '',' 'TYPE'
  '('
  'NAME' 'etermine' transactionManager '',' propertiesDefinition ')')'

propertiesDefinition ::= 'PROPERTIES' '('
  key 'value (',' key 'value)* ')'

defaultTransactionType ::= string

transactionManager ::= string

key ::= string

value ::= literal
```

**Supplement**

- defaultTransactionType support LOCAL, XA, BASE
- transactionManager support Atomikos and Narayana
Example

- Alter transaction rule

```sql
ALTER TRANSACTION RULE(
    DEFAULT="XA", TYPE(NAME="Narayana", PROPERTIES("databaseName"="jbossts", "host"=
        "127.0.0.1"))
);
```

**SHOW SQL_PARSER RULE**

Description

The `SHOW SQL_PARSER RULE` syntax is used to query sql parser rule configuration.

Syntax

```
ShowSqlParserRule ::= 
    'SHOW' 'SQL_PARSER' 'RULE'
```

Return Value Description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parse_tree_cache</td>
<td>parse tree cache configuration</td>
</tr>
<tr>
<td>sql_statement_cache</td>
<td>SQL statement cache configuration</td>
</tr>
</tbody>
</table>

9.2. ShardingSphere-Proxy 300
**Example**

- Query sql parser rule configuration

```
SHOW SQL_PARSER RULE;
```

```mysql
mysql> SHOW SQL_PARSER RULE;
+---------------------------------------------------------------------+---------------------------------------------------------------------
| parse_tree_cache | sql_statement_cache |
+------------------+---------------------+---------------------------------------------------------------------+---------------------------------------------------------------------
| initialCapacity: 128, maximumSize: 1024 | initialCapacity: 2000, maximumSize: 65535 |
+---------------------------------------------------------------------+---------------------------------------------------------------------
1 row in set (0.05 sec)
```

**Alter SQL_PARSER Rule**

**Description**

The ALTER SQL_PARSER RULE syntax is used to alter the SQL parser rule configuration.

**Syntax**

```
AlterSqlParserRule ::= 
  'ALTER' 'SQL_PARSER' 'RULE' '(' sqlParserRuleDefinition ')' 
sqlParserRuleDefinition ::= 
  parseTreeCacheDefinition? (',' sqlStatementCacheDefinition)? 
parseTreeCacheDefinition ::= 
  'PARSE_TREE_CACHE' '(' cacheOption ')' 
```
sqlStatementCacheDefinition ::=  
'SQL_STATEMENT_CACHE' '(
  cacheOption
)'  

cacheOption ::=  
  ('INITIAL_CAPACITY' '=' initialCapacity)? (','? 'MAXIMUM_SIZE' '=' maximumSize)?  

initialCapacity ::=  
  int  

maximumSize ::=  
  int

Note

- PARSE_TREE_CACHE: local cache configuration of the syntax tree.
- SQL_STATEMENT_CACHE: the local cache of SQL statement.

Example

- Alter SQL parser rule

```
ALTER SQL_PARSER RULE (  
  PARSE_TREE_CACHE(INITIAL_CAPACITY=128, MAXIMUM_SIZE=1024),  
  SQL_STATEMENT_CACHE(INITIAL_CAPACITY=2000, MAXIMUM_SIZE=65535)
);
```

SHOW TRAFFIC RULE

Description

The SHOW TRAFFIC RULE syntax is used to query specified dual routing rule.

Syntax

ShowTrafficRule ::= 'SHOW' 'TRAFFIC' ('RULES' | 'RULE' ruleName)?
ruleName ::= identifier

Supplement

- When ruleName not specified, the default is show all traffic rules

ReturnValueDescription

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>traffic rule name</td>
</tr>
<tr>
<td>labels</td>
<td>compute node labels</td>
</tr>
<tr>
<td>algorithm_type</td>
<td>traffic algorithm type</td>
</tr>
<tr>
<td>algorithm_props</td>
<td>traffic algorithm properties</td>
</tr>
<tr>
<td>load_balancer_type</td>
<td>load balancer type</td>
</tr>
<tr>
<td>load_balancer_props</td>
<td>load balancer properties</td>
</tr>
</tbody>
</table>

Example

- Query specified traffic rule

SHOW TRAFFIC RULE sql_match_traffic;

mysql> SHOW TRAFFIC RULE sql_match_traffic;
+-------------------+--------+----------------+------------------------------------+
<table>
<thead>
<tr>
<th>name</th>
<th>labels</th>
<th>algorithm_type</th>
<th>algorithm_props</th>
<th>load_balancer_type</th>
<th>load_balancer_props</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
+-------------------+--------+----------------+------------------------------------+

### 9.2. ShardingSphere-Proxy

#### SHOW TRAFFIC RULES;

```sql
mysql> SHOW TRAFFIC RULES;
```

<table>
<thead>
<tr>
<th>name</th>
<th>labels</th>
<th>algorithm_type</th>
<th>algorithm_props</th>
<th>load_balancer_type</th>
<th>load_balancer_props</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_match_traffic</td>
<td>OLTP</td>
<td>SQL_MATCH</td>
<td>sql=SELECT * FROM t_order WHERE order_id = 1; UPDATE t_order SET order_id = 5;</td>
<td>RANDOM</td>
<td></td>
</tr>

**ALTER TRAFFIC RULE**

**Description**

The **ALTER TRAFFIC RULE** syntax is used to alter dual routing rule.

**Syntax**

```plaintext
AlterTrafficRule ::=  
  'ALTER' 'TRAFFIC' 'RULE' 'LABELS' '(', lableName ',', 'TRAFFIC_ALGORITHM' '(', 'TYPE' 'NAME' = trafficAlgorithmTypeName ',', propertiesDefinition)? '],' 'LOAD_BALANCER' '(', 'TYPE' 'NAME' = loadBalancerName ',', propertiesDefinition)? ',' 'PROPERTIES' '(' key '=' value ')', key '=' value)* ')

lableName ::= 
  identifier 

trafficAlgorithmDefinition ::= 
  'TRAFFIC_ALGORITHM' '(', 'TYPE' 'NAME' = trafficAlgorithmTypeName ',', propertiesDefinition)? ',' '

loadBalancerDefinition ::= 
  'LOAD_BALANCER' '(', 'TYPE' 'NAME' = loadBalancerName ',', propertiesDefinition)? ',' '

propertiesDefinition ::= 
  'PROPERTIES' '(' key '=' value ')', key '=' value)* '

trafficAlgorithmTypeName ::= 
  string 

loadBalancerTypeName ::= 
  string 

key ::= 
  string 

value ::= 
  literal
```
Supplement

- TRAFFIC_ALGORITHM support SQL_MATCH and SQL_HINT two types;
- LOAD_BALANCER support RANDOM and ROUND_ROBIN two types.

Example

- Alter dual routing rule

```
ALTER traffic_rule sql_match_traffic {
  labels (oltp),
  traffic_algorithm (type (name = "SQL_MATCH", properties ("sql" = "SELECT * FROM t_order WHERE order_id = 1; UPDATE t_order SET order_id = 5;")))
  load_balancer (type (name = "RANDOM"));

CIRCUIT BREAKER

This chapter describes the syntax of Circuit Breaker.

ALTER READWRITE_SPLITTING RULE ENABLE/DISABLE

Description

The ALTER READWRITE_SPLITTING RULE ENABLE/DISABLE syntax is used enable/disable a specified read source for specified readwrite-splitting rule.
**Syntax**

```plaintext
AlterReadWriteSplittingRule ::= 'ALTER' 'READWRITE_SPLITTING' 'RULE' groupName ('ENABLE' | 'DISABLE') storageUnitName 'FROM' databaseName

groupName ::= identifier
storageUnitName ::= identifier
databaseName ::= identifier
```

**Supplement**

- When `databaseName` is not specified, the default is the currently used DATABASE. If DATABASE is not used, `No database selected` will be prompted.

**Example**

- Disable a specified read source for specified readwrite-splitting rule in specified database

```sql
ALTER READWRITE_SPLITTING RULE ms_group_0 DISABLE read_ds_0 FROM sharding_db;
```

- Enable a specified read source for specified readwrite-splitting rule in specified database

```sql
ALTER READWRITE_SPLITTING RULE ms_group_0 ENABLE read_ds_0 FROM sharding_db;
```

- Disable a specified read source for specified readwrite-splitting rule in current database

```sql
ALTER READWRITE_SPLITTING RULE ms_group_0 DISABLE read_ds_0;
```

- Enable a specified read source for specified readwrite-splitting rule in current database

```sql
ALTER READWRITE_SPLITTING RULE ms_group_1 ENABLE read_ds_0;
```

SHOW STATUS FROM READWRITE_SPLITTING RULE

Description

The SHOW STATUS FROM READWRITE_SPLITTING RULE syntax is used to query readwrite-splitting storage unit status for specified readwrite-splitting rule in specified database.

Syntax

ShowStatusFromReadwriteSplittingRule ::=  
  'SHOW' 'STATUS' 'FROM' 'READWRITE_SPLITTING' ('RULES' | 'RULE' groupName) (FROM databaseName)?

groupName ::= identifier

databaseName ::= identifier

Supplement

- When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted.

Return Value Description

<table>
<thead>
<tr>
<th>Columns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>storage_unit</td>
<td>storage unit name</td>
</tr>
<tr>
<td>status</td>
<td>storage unit status</td>
</tr>
</tbody>
</table>
Example

- Query readwrite-splitting storage unit status for specified readwrite-splitting rule in specified database.

```sql
SHOW STATUS FROM READWRITE_SPLITTING RULE ms_group_0 FROM sharding_db;
```

```
mysql> SHOW STATUS FROM READWRITE_SPLITTING RULE ms_group_0 FROM sharding_db;
+-----------------+----------+
| storage_unit    | status   |
|-----------------+----------+
| ds_0            | disabled |
+-----------------+----------+
1 rows in set (0.01 sec)
```

- Query all readwrite-splitting storage unit from specified database

```sql
SHOW STATUS FROM READWRITE_SPLITTING RULES FROM sharding_db;
```

```
mysql> SHOW STATUS FROM READWRITE_SPLITTING RULES FROM sharding_db;
+-----------------+----------+
| storage_unit    | status   |
|-----------------+----------+
| ds_0            | disabled |
+-----------------+----------+
1 rows in set (0.01 sec)
```

- Query readwrite-splitting storage unit status for specified readwrite-splitting rule in current database

```sql
SHOW STATUS FROM READWRITE_SPLITTING RULE ms_group_0;
```

```
mysql> SHOW STATUS FROM READWRITE_SPLITTING RULE ms_group_0;
+-----------------+----------+
| storage_unit    | status   |
|-----------------+----------+
| ds_0            | disabled |
+-----------------+----------+
1 rows in set (0.01 sec)
```

- Query all readwrite-splitting storage unit from current database

```sql
SHOW STATUS FROM READWRITE_SPLITTING RULES;
```

```
mysql> SHOW STATUS FROM READWRITE_SPLITTING RULES;
+-----------------+----------+
| storage_unit    | status   |
|-----------------+----------+

SHOW COMPUTE NODES

Description

The SHOW COMPUTE NODES syntax is used to query compute nodes information.

### Syntax

```
SHOW COMPUTE NODES
```

### Return Value Description

<table>
<thead>
<tr>
<th>Columns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance_id</td>
<td>instance id</td>
</tr>
<tr>
<td>instance_type</td>
<td>instance type</td>
</tr>
<tr>
<td>host</td>
<td>host</td>
</tr>
<tr>
<td>port</td>
<td>port</td>
</tr>
<tr>
<td>status</td>
<td>status</td>
</tr>
<tr>
<td>mode_type</td>
<td>mode type</td>
</tr>
<tr>
<td>worker_id</td>
<td>worker id</td>
</tr>
<tr>
<td>labels</td>
<td>labels</td>
</tr>
<tr>
<td>version</td>
<td>version</td>
</tr>
</tbody>
</table>
Example

```
mysql> SHOW COMPUTE NODES;
+----------+------------+-----------------+--------+---------------------+
| instance_id | instance_type | host     | port | status |
| mode_type   | worker_id   | labels | version |
+----------+------------+--------+-------+
| 3e84d33e-cb97-42f2-b6ce-f78f98d9 | PROXY | 127.0.0.1 | 3307 | OK |
| Cluster   | -1 | | 5.4.2 |

ENABLE/DISABLE COMPUTE NODE

Description

The ENABLE/DISABLE COMPUTE NODE syntax is used enable/disable a specified proxy instance

Syntax

```
ENABLEDisableComputeNode ::= ('ENABLE' | 'DISABLE') 'COMPUTE' 'NODE' instanceId

instanceId ::= string
```
Supplement

- `instanceId` needs to be obtained through `SHOW COMPUTE NODES` syntax query
- The currently in-use proxy instance cannot be disabled

Example

- Disable a specified proxy instance

```sql
DISABLE COMPUTE NODE '734bb086-b15d-4af0-be87-2372d8b6a0cd';
```

- Enable a specified proxy instance

```sql
ENABLE COMPUTE NODE '734bb086-b15d-4af0-be87-2372d8b6a0cd';
```

**LABEL|RELABEL COMPUTE NODES**

Description

The `LABEL|RELABEL COMPUTE NODES` syntax is used to label `PROXY` instance.

Syntax

```
LabelRelabelComputeNodes ::= ('LABEL' | 'RELABEL') 'COMPUTE' 'NODE' instance_id 'WITH' labelName
```

```
instance_id ::= string
labelName ::= identifier
```
Supplement

- needs to be obtained through SHOW COMPUTE NODES syntax query
- RELABEL is used to relabel PROXY instance

Example

- Label PROXY instance

```
LABEL COMPUTE NODE "0699e636-ade9-4681-b37a-65240c584bb3" WITH label_1;
```

- Relabel PROXY instance

```

UNLABEL COMPUTE NODES

Description

The UNLABEL COMPUTE NODES syntax is used to remove specified label from PROXY instance.

Syntax

```
UnlabelComputeNode ::= 'UNLABEL' 'COMPUTE' 'NODE' instance_id 'WITH' labelName
instance_id ::= string
labelName ::= identifier
```
Supplement

- needs to be obtained through `SHOW COMPUTE NODES` syntax query

Example

- Remove specified label from PROXY instance

```
UNLABEL COMPUTE NODE "0699e636-ade9-4681-b37a-65240c584bb3" WITH label_1;

MIGRATUION

This chapter describes the syntax of migration.

SHOW MIGRATION RULE

Description

The `SHOW MIGRATION RULE` syntax is used to query migration rule.

Syntax

```
ShowMigrationRule ::= 'SHOW' 'MIGRATION' 'RULE'
```
Return Value Description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>read</td>
<td>Data reading configuration</td>
</tr>
<tr>
<td>write</td>
<td>Data writing configuration</td>
</tr>
<tr>
<td>stream_channel</td>
<td>Data channel</td>
</tr>
</tbody>
</table>

Example

- Query migration rule

```sql
SHOW MIGRATION RULE;
```

```
mysql> SHOW MIGRATION RULE;
+--------------------------------------------------------------+-------------------+-------------------------------------------------------+
| read | write                        |
| stream_channel |
+--------------------------------------------------------------+-------------------+-------------------------------------------------------+
| {
  "workerThread":20,
  "batchSize":1000,
  "shardingSize":10000000
} | {
  "workerThread":20,
  "batchSize":1000
} | {
  "type":"MEMORY",
  "props":{
    "block-queue-size":"2000"
  }

ALTER MIGRATION RULE

Description

The ALTER MIGRATION RULE syntax is used to alter migration rule.
### Syntax

```plaintext
AlterMigrationRule ::= 'ALTER' 'MIGRATION' 'RULE' ('(' (readConfiguration ',')? (writeConfiguration ',', ')')? (dataChannel)? ')')?

readConfiguration ::= 'READ' '(' ('WORKER_THREAD' '=' workerThreadPoolSize ',')? ('BATCH_SIZE' '=' batchSize ',')? ('SHARDING_SIZE' '=' shardingSize ',')? (rateLimiter)? ')'?

writeConfiguration ::= 'WRITE' '(' ('WORKER_THREAD' '=' workerThreadPoolSize ',')? ('BATCH_SIZE' '=' batchSize ',')? ('SHARDING_SIZE' '=' shardingSize ',')? (rateLimiter)? ')'?

dataChannel ::= 'STREAM_CHANNEL' '(' 'TYPE' '(' 'NAME' '=' algorithmName ',' propertiesDefinition ')')

workerThreadPoolSize ::= int

batchSize ::= int

shardingSize ::= int

rateLimiter ::= 'RATE_LIMITER' '(' 'TYPE' '(' 'NAME' '=' algorithmName ',' propertiesDefinition ')')

algorithmName ::= string

propertiesDefinition ::= 'PROPERTIES' '(' key '=' value (',' key '=' value)* ')' 

key ::= string

value ::= literal
```
Supplement

- ALTER MIGRATION RULE able to modify only one configuration in the data migration rule without affecting other configurations.

Example

- Alter migration rule

```sql
ALTER MIGRATION RULE (
  READ (WORKER_THREAD=20, BATCH_SIZE=1000, SHARDING_SIZE=10000000, RATE_LIMITER (TYPE(NAME='QPS',PROPERTIES('qps'='500')))),
  WRITE (WORKER_THREAD=20, BATCH_SIZE=1000, RATE_LIMITER (TYPE(NAME='TPS', PROPERTIES('tps'='2000')))),
  STREAM_CHANNEL (TYPE(NAME='MEMORY',PROPERTIES('block-queue-size'='2000')));
)
```

- Alter read configuration only in migration rule

```sql
ALTER MIGRATION RULE (
  READ (WORKER_THREAD=20, BATCH_SIZE=1000, SHARDING_SIZE=10000000, RATE_LIMITER (TYPE(NAME='QPS',PROPERTIES('qps'='500')))));
```

- Alter write configuration only in migration rule

```sql
ALTER MIGRATION RULE (
  WRITE (WORKER_THREAD=20, BATCH_SIZE=1000, SHARDING_SIZE=10000000, RATE_LIMITER (TYPE(NAME='QPS',PROPERTIES('qps'='500')))));
```

- Alter stream channel configuration in migration rule

```sql
ALTER MIGRATION RULE (
  STREAM_CHANNEL (TYPE(NAME='MEMORY',PROPERTIES('block-queue-size'='2000')));
```

REGISTER MIGRATION SOURCE STORAGE UNIT

Description

The REGISTER MIGRATION SOURCE STORAGE UNIT syntax is used to register migration source storage unit for the currently connection.

Syntax

```
RegisterStorageUnit ::= 'REGISTER' 'MIGRATION' 'SOURCE' 'STORAGE' 'UNIT' storageUnitDefinition (',' storageUnitDefinition)*

storageUnitDefinition ::= StorageUnitName '(' 'URL' '=' url ', 'USER' '=' user (',' 'PASSWORD' '=' password)? (',' propertiesDefinition)? ')

storageUnitName ::= identifier

url ::= string

user ::= string

password ::= string

propertiesDefinition ::= 'PROPERTIES' '(' ( key '=' value ) (',' key '=' value )* ')' 

key ::= string

value ::= literal
```
Supplement

• Confirm that the registered migration source storage unit can be connected normally, otherwise it will not be added successfully;
• storageUnitName is case-sensitive;
• storageUnitName needs to be unique within the current connection;
• storageUnitName name only allows letters, numbers and _, and must start with a letter;
• poolProperty is used to customize connection pool parameters, key must be the same as the connection pool parameter name, value supports int and String types;
• When password contains special characters, it is recommended to use the string form; For example, the string form of password@123 is "password@123".
• The data migration source storage unit currently only supports registration using URL, and temporarily does not support using HOST and PORT.

Example

• Register migration source storage unit

```java
REGISTER MIGRATION SOURCE STORAGE UNIT ds_0 (URL="jdbc:mysql://127.0.0.1:3306/migration_ds_0?serverTimezone=UTC&useSSL=false", USER="root", PASSWORD="root");
```

• Register migration source storage unit and set connection pool parameters

```java
REGISTER MIGRATION SOURCE STORAGE UNIT ds_0 (URL="jdbc:mysql://127.0.0.1:3306/migration_ds_0?serverTimezone=UTC&useSSL=false", USER="root", PASSWORD="root", PROPERTIES("minPoolSize"="1", "maxPoolSize"="20", "idleTimeout"="60000")
```

UNREGISTER MIGRATION SOURCE STORAGE UNIT

Description

The UNREGISTER MIGRATION SOURCE STORAGE UNIT syntax is used to unregister migration source storage unit from the current connection.

Syntax

```
UnregisterMigrationSourceStorageUnit ::= 'UNREGISTER' 'MIGRATION' 'SOURCE' 'STORAGE' 'UNIT' storageUnitName (',' storageUnitName)*

storageUnitName ::= identifier
```

Supplement

- UNREGISTER MIGRATION SOURCE STORAGE UNIT will only unregister storage unit in Proxy, the real data source corresponding to the storage unit will not be dropped;

Example

- Drop a migration source storage unit

```sql
UNREGISTER MIGRATION SOURCE STORAGE UNIT ds_0;
```

- Drop multiple migration source storage units

```sql
UNREGISTER MIGRATION SOURCE STORAGE UNIT ds_1, ds_2;
```

SHOW MIGRATION SOURCE STORAGE UNITS

Description

The SHOW MIGRATION SOURCE STORAGE UNITS syntax is used to query the registered migration source storage units.

Syntax

```
ShowStorageUnit ::= 'SHOW' 'MIGRATION' 'SOURCE' 'STORAGE' 'UNITS'
```

Return Value Description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Storage unit name</td>
</tr>
<tr>
<td>type</td>
<td>Storage unit type</td>
</tr>
<tr>
<td>host</td>
<td>Storage unit host</td>
</tr>
<tr>
<td>port</td>
<td>Storage unit port</td>
</tr>
<tr>
<td>db</td>
<td>Database name</td>
</tr>
<tr>
<td>attribute</td>
<td>Storage unit attribute</td>
</tr>
</tbody>
</table>

### Example

- Query registered migration source storage units

```
SHOW MIGRATION SOURCE STORAGE UNITS;
```

```

**MIGRATE TABLE INTO**

**Description**

MIGRATE TABLE INTO syntax is used to migration table from source to target

**Syntax**

```
MigrateTableInto ::= 'MIGRATE' 'TABLE' migrationSource '.' tableName 'INTO' (databaseName '.')? tableName

migrationSource ::= identifier

databaseName ::= identifier

tableName ::= identifier
```
Supplement

- When `databaseName` is not specified, the default is the currently used `DATABASE`. If `DATABASE` is not used, `No database selected` will be prompted.

Example

- Migrate table from source to current database

  ```
  MIGRATE TABLE ds_0.t_order INTO t_order;
  ```

- Migrate table from source to specified database

  ```
  UNREGISTER MIGRATION SOURCE STORAGE UNIT ds_1, ds_2;
  ```

SHOW MIGRATION CHECK ALGORITHM

Description

The SHOW MIGRATION RULE syntax is used to query migration check algorithm.

Syntax

ShowMigrationCheckAlgorithm ::= 'SHOW' 'MIGRATION' 'CHECK' 'ALGORITHMS'

Return Value Description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>migration check algorithm type</td>
</tr>
<tr>
<td>supported_database_types</td>
<td>supported database type</td>
</tr>
<tr>
<td>description</td>
<td>Description of migration check algorithm</td>
</tr>
</tbody>
</table>
Example

• Query migration check algorithm

```sql
SHOW MIGRATION CHECK ALGORITHMS;
```

```sql
mysql> SHOW MIGRATION CHECK ALGORITHMS;
+-----------------------+--------------------------------------------------------------+-----
| type                  | supported_database_types                                    |     |

CHECK MIGRATION

Description

The CHECK MIGRATION LIST syntax is used to check data consistancy in migration job.

Syntax

```sql
ShowMigrationList ::=  
  'CHECK' 'MIGRATION' migrationJobId 'BY' 'TYPE' '.nama:':migrationCheckAlgorithmType ')
```

```sql
migrationJobId ::= 
  string
```
migrationCheckAlgorithmType ::= string

**Supplement**

- migrationJobId needs to be obtained through `SHOW MIGRATION LIST` syntax query
- migrationCheckAlgorithmType needs to be obtained through `SHOW MIGRATION CHECK ALGORITHMS` syntax query

**Example**

- check data consistancy in migration job

```sql
CHECK MIGRATION 'j01016e501b498ed1b2c373a2e85e2529a6' BY TYPE (NAME='CRC32_MATCH ');
```

**Reserved word**

`CHECK, MIGRATION, BY, TYPE`

**Related links**

- Reserved word
- `SHOW MIGRATION LIST`
- `SHOW MIGRATION CHECK ALGORITHMS`

**SHOW MIGRATION CHECK STATUS**

**Description**

The `SHOW MIGRATION CHECK STATUS` syntax is used to query migration check status for specified migration job.
Syntax

```plaintext
ShowMigrationCheckStatus ::= 'SHOW' 'MIGRATION' 'CHECK' 'STATUS' migrationJobId
```

```plaintext
migrationJobId ::= string
```

Supplement

- migrationJobId needs to be obtained through `SHOW MIGRATION LIST` syntax query

Return Value Description

<table>
<thead>
<tr>
<th>Columns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tables</td>
<td>migration check table</td>
</tr>
<tr>
<td>result</td>
<td>check result</td>
</tr>
<tr>
<td>finished_percentage</td>
<td>check finished finished_percentage</td>
</tr>
<tr>
<td>remaining_seconds</td>
<td>check remaining time</td>
</tr>
<tr>
<td>check_begin_time</td>
<td>check begin time</td>
</tr>
<tr>
<td>check_end_time</td>
<td>check end time</td>
</tr>
<tr>
<td>error_message</td>
<td>error message</td>
</tr>
</tbody>
</table>

Example

- Query migration check status

```plaintext
SHOW MIGRATION CHECK STATUS 'j010180026753ef0e25d3932d94d1673ba551';
```

```plaintext
mysql> SHOW MIGRATION CHECK STATUS 'j010180026753ef0e25d3932d94d1673ba551';
+-----------------------------------+------------------------+------------------------------+------------------------+-------------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+
<table>
<thead>
<tr>
<th>tables</th>

SPI IMPLEMENTATION

This chapter describes the syntax of show SPI implementations.

Sharding

This chapter describes the syntax of sharding RAL.

SHOW SHARDING ALGORITHM IMPLEMENTATIONS

Description

The SHOW SHARDING ALGORITHM IMPLEMENTATIONS syntax is used to query all the implementations of the interface org.apache.shardingsphere.sharding.spi.ShardingAlgorithm.

Syntax

showShardingAlgorithmImplementations ::= 'SHOW' 'SHARDING' 'ALGORITHM' 'IMPLEMENTATIONS'
Return Value Description

<table>
<thead>
<tr>
<th>Columns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>class name of the implementation</td>
</tr>
<tr>
<td>type</td>
<td>type of the implementation</td>
</tr>
<tr>
<td>class_path</td>
<td>full class name of the implementation</td>
</tr>
</tbody>
</table>

Example

- Query all the implementations for org.apache.shardingsphere.sharding.spi.ShardingAlgorithm interface

```sql
SHOW SHARDING ALGORITHM IMPLEMENTATIONS;
```

```
<table>
<thead>
<tr>
<th>name</th>
<th>type</th>
<th>class_path</th>
</tr>

SHOW READ QUERY LOAD BALANCE ALGORITHM IMPLEMENTATIONS

Description

The SHOW READ QUERY LOAD BALANCE ALGORITHM IMPLEMENTATIONS syntax is used to query all the implementations of the interface org.apache.shardingsphere.readwritesplitting.spi.ReadQueryLoadBalanceAlgorithm.

Syntax

```
showReadQueryLoadBalanceAlgorithmImplementations ::= 
'SHOW' 'READ' 'QUERY' 'LOAD' 'BALANCE' 'ALGORITHM' 'IMPLEMENTATIONS'
```

Return Value Description

<table>
<thead>
<tr>
<th>Columns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>class name of the implementation</td>
</tr>
<tr>
<td>type</td>
<td>type of the implementation</td>
</tr>
<tr>
<td>class_path</td>
<td>full class name of the implementation</td>
</tr>
</tbody>
</table>

Example

- Query all the implementations for org.apache.shardingsphere.readwritesplitting.spi.ReadQueryLoadBalanceAlgorithm interface

```
SHOW READ QUERY LOAD BALANCE ALGORITHM IMPLEMENTATIONS
```
### SHOW READ QUERY LOAD BALANCE ALGORITHM IMPLEMENTATIONS;

<table>
<thead>
<tr>

<td>org.apache.shardingsphere.sharding.algorithm.sharding.hint.HintInlineShardingAlgorithm</td>
</tr>
</tbody>
</table>

10 rows in set (0.52 sec)

Supplement

For some commonly used SPI interface implementations, ShardingSphere provides syntax sugar functions to simplify operations.

The currently provided SPI interfaces with syntactic sugar functions are as follows:

• Show implementations of org.apache.shardingsphere.sharding.spl. ShardingAlgorithm: \( \text{SHOW SHARDING ALGORITHM IMPLEMENTATIONS} \)
• Show implementations of org.apache.shardingsphere.readwritesplitting.spi.
  ReadQueryLoadBalanceAlgorithm:  
  SHOW READ QUERY LOAD BALANCE ALGORITHM IMPLEMENTATIONS

• Show implementations of org.apache.shardingsphere.encrypt.spi.
  EncryptAlgorithm:  
  SHOW ENCRYPT ALGORITHM IMPLEMENTATIONS

• Show implementations of org.apache.shardingsphere.mask.spi.MaskAlgorithm: 
  SHOW MASK ALGORITHM IMPLEMENTATIONS

• Show implementations of org.apache.shardingsphere.shadow.spi.
  ShadowAlgorithm:  
  SHOW SHADOW ALGORITHM IMPLEMENTATIONS

• Show implementations of org.apache.shardingsphere.keygen.core.algorithm.
  KeyGenerateAlgorithm:  
  SHOW KEY GENERATE ALGORITHM IMPLEMENTATIONS

**SET DIST VARIABLE**

**Description**

The SET DIST VARIABLE syntax is used to set system variables. 

### Syntax

```
SetDistVariable ::= 
  'SET' 'DIST' 'VARIABLE' (proxyPropertyName '=' proxyPropertyValue | 'agent_plugins_enabled' '=' agentPluginsEnabled)
```

- `proxyPropertyName` ::= identifier
- `proxyPropertyValue` ::= literal
- `agentPluginsEnabled` ::= boolean

**Supplement**

- `proxy_property_name` is one of `properties configuration` of PROXY, name is split by underscore
- `agent_plugins_enabled` is used to set the agent plugins enable status, the default value is FALSE
- `system_log_level` is the system log level, only affects the log printing of PROXY, the default value is INFO

**Example**

- Set property configuration of Proxy
  
  ```
  SET DIST VARIABLE sql_show = true;
  ```

- Set agent plugin enable status
SET DIST VARIABLE agent_plugins_enabled = TRUE;

SHOW DIST VARIABLE

Description

The SHOW DIST VARIABLE syntax is used to query PROXY system variables configuration.

Syntax

ShowDistVariable ::= 'SHOW' 'DIST' ('VARIABLES' ('LIKE' likePattern)? | 'VARIABLE' 'WHERE' 'NAME' '=' variableName)

likePattern ::= string

variableName ::= identifier

Return Value Description

<table>
<thead>
<tr>
<th>Columns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>variable_name</td>
<td>system variable name</td>
</tr>
<tr>
<td>variable_value</td>
<td>system variable value</td>
</tr>
</tbody>
</table>
Supplement

- When variableName is not specified, the default is query all PROXY variables configuration.

Example

- Query all system variables configuration of PROXY

```sql
SHOW DIST VARIABLES;
```

```
+-----------------+-----------------+
| variable_name   | variable_value  |
+-----------------+-----------------+
| agent_plugins_enabled | true         | 33071 |
| cached_connections | 0             |      |
| check_table_metadata_enabled | false     |      |

REFRESH TABLE METADATA

Description

The REFRESH TABLE METADATA syntax is used to refresh table metadata.

Syntax

RefreshTableMetadata ::= 'REFRESH' 'TABLE' 'METADATA' (tableName | tableName 'FROM' 'STORAGE' 'UNIT' storageUnitName ('SCHEMA' schemaName)??)

tableName ::= identifier

storageUnitName ::= identifier

schemaName ::= identifier

Supplement

• When tableName and storageUnitName is not specified, the default is to refresh all table metadata.

• refresh table metadata need to use DATABASE. If DATABASE is not used, No database selected will be prompted.

• If there are no tables in the schema, the schema will be deleted.
Example

- Refresh specified table’s metadata in specified schema of a specified storage unit

```sql
REFRESH TABLE METADATA t_order FROM STORAGE UNIT ds_1 SCHEMA db_schema;
```

- Refresh all tables’ metadata in specified schema of a specified storage unit

```sql
REFRESH TABLE METADATA FROM STORAGE UNIT ds_1 SCHEMA db_schema;
```

- Refresh metadata for specified table in specified storage unit

```sql
REFRESH TABLE METADATA t_order FROM STORAGE UNIT ds_1;
```

- Refresh metadata for specified table

```sql
REFRESH TABLE METADATA t_order;
```

- Refresh all table metadata

```sql
REFRESH TABLE METADATA;
```

Reserved word

```sql
REFRESH, TABLE, METADATA, FROM, STORAGE, UNIT
```

**REFRESH DATABASE METADATA FROM GOVERNANCE CENTER**

Description

The **REFRESH DATABASE METADATA** syntax is used to refresh the metadata of the local logic database.

Syntax

```sql
RefreshDatabaseMetadata ::= 'FORCE'? 'REFRESH' 'DATABASE' 'METADATA' databaseName?

databaseName ::= identifier
```
Supplement

- When `databaseName` is not specified, the default is to refresh all database metadata.
- When using `FORCE` to refresh metadata, the latest metadata will be obtained locally and written to the governance center. If without `FORCE`, it will be pulled from the governance center.

Example

- Refresh metadata for specified database

```sql
REFRESH DATABASE METADATA sharding_db;
```

- Refresh all database metadata

```sql
REFRESH DATABASE METADATA;
```

- Force refresh all database metadata

```sql
FORCE REFRESH DATABASE METADATA;
```

SHOW TABLE METADATA

Description

The `SHOW TABLE METADATA` syntax is used to query table metadata.

Syntax

```
ShowTableMetadata ::= 'SHOW' 'TABLE' 'METADATA' tableName (',' tableName)* ('FROM' databaseName)?
```

```
tableName ::= identifier
```

```
databaseName ::= identifier
```
Return Value Description

<table>
<thead>
<tr>
<th>Columns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schema_name</td>
<td>database name</td>
</tr>
<tr>
<td>table_name</td>
<td>table name</td>
</tr>
<tr>
<td>type</td>
<td>metadata type</td>
</tr>
<tr>
<td>name</td>
<td>metadata name</td>
</tr>
</tbody>
</table>

Supplement

- When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted.

Example

- Query metadata of multiple tables from specified database

```sql
SHOW TABLE METADATA t_order, t_order_1 FROM sharding_db;
```

```
+-------------------+------------+--------+----------+
| schema_name       | table_name | type   | name     |
|-------------------|------------|--------+----------|
| sharding_db       | t_order_1  | COLUMN | order_id  |
| sharding_db       | t_order_1  | COLUMN | user_id   |
| sharding_db       | t_order_1  | COLUMN | status    |
| sharding_db       | t_order_1  | INDEX  | PRIMARY   |
| sharding_db       | t_order    | COLUMN | order_id  |
| sharding_db       | t_order    | COLUMN | user_id   |
| sharding_db       | t_order    | INDEX  | PRIMARY   |
+-------------------+------------+--------+----------+
8 rows in set (0.01 sec)
```

- Query metadata of one table from specified database

```sql
SHOW TABLE METADATA t_order FROM sharding_db;
```

```
+-------------------+------------+--------+----------+
| schema_name       | table_name | type   | name     |
+-------------------+------------+--------+----------+
```

9.2. ShardingSphere-Proxy
• Query metadata of multiple tables from current database

```sql
SHOW TABLE METADATA t_order, t_order_1;
```

```
+-------------------+------------+--------+----------+
| schema_name | table_name | type | name |
+-------------------+------------+--------+----------+
| sharding_db | t_order_1 | COLUMN | order_id |
| sharding_db | t_order_1 | COLUMN | user_id |
| sharding_db | t_order_1 | COLUMN | status |
| sharding_db | t_order_1 | INDEX | PRIMARY |
| sharding_db | t_order | COLUMN | order_id |
| sharding_db | t_order | COLUMN | user_id |
| sharding_db | t_order | COLUMN | status |
| sharding_db | t_order | INDEX | PRIMARY |
+-------------------+------------+--------+----------+
```

8 rows in set (0.00 sec)

• Query metadata of one table from current database

```sql
SHOW TABLE METADATA t_order;
```

```
+-------------------+------------+--------+----------+
| schema_name | table_name | type | name |
+-------------------+------------+--------+----------+
| sharding_db | t_order | COLUMN | order_id |
| sharding_db | t_order | COLUMN | user_id |
| sharding_db | t_order | COLUMN | status |
| sharding_db | t_order | INDEX | PRIMARY |
| sharding_db | t_order | COLUMN | order_id |
| sharding_db | t_order | COLUMN | user_id |
| sharding_db | t_order | COLUMN | status |
| sharding_db | t_order | INDEX | PRIMARY |

EXPORT DATABASE CONFIGURATION

Description

The EXPORT DATABASE CONFIGURATION syntax is used to export storage units and rule configurations to YAML format.

Syntax

```plaintext
ExportDatabaseConfiguration ::= 'EXPORT' 'DATABASE' 'CONFIGURATION' ('FROM' databaseName)? ('TO' 'FILE' filePath)?
```

databaseName ::= identifier

filePath ::= string

Supplement

- When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted.
- When filePath is not specified, the storage units and rule configurations will export to screen. ### Example
- Export storage units and rule configurations from specified database to specified file path

```
EXPORT DATABASE CONFIGURATION FROM sharding_db TO FILE "/xxx/config_sharding_db.yaml";
```

- Export storage units and rule configurations from specified database to screen

```
EXPORT DATABASE CONFIGURATION FROM sharding_db;
```
mysql> EXPORT DATABASE CONFIGURATION FROM sharding_db;
+
<table>
<thead>
<tr>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>+--------</td>
</tr>
</tbody>
</table>
| databaseName: sharding_db
| dataSources:

IMPORT DATABASE CONFIGURATION

Description

The IMPORT DATABASE CONFIGURATION syntax is used to import YAML configuration to specified database.
Syntax

ExportDatabaseConfiguration ::= 'IMPORT' 'DATABASE' 'CONFIGURATION' FROM 'FILE' filePath

filePath ::= string

Supplement

- When databaseName is not specified, the default is the currently used DATABASE. If DATABASE is not used, No database selected will be prompted.
- The IMPORT DATABASE CONFIGURATION syntax only supports import operations on empty database.

Example

- Import the configuration in YAML into the specified database

IMPORT DATABASE CONFIGURATION FROM FILE "/xxx/config_sharding_db.yaml";

- Import the configuration in YAML into the current database

IMPORT DATABASE CONFIGURATION FROM FILE "/xxx/config_sharding_db.yaml";

SHOW RULES USED STORAGE UNIT

Description

The SHOW RULES USED STORAGE UNIT syntax is used to query the rules for using the specified storage unit in specified database.
Syntax

```
SHOW 'RULES' 'USED' 'STORAGE' 'UNIT' storageUnitName (FROM databaseName)?
```

```
storageUnitName ::= identifier
```

```
databaseName ::= identifier
```

Return Value Description

<table>
<thead>
<tr>
<th>Columns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>rule type</td>
</tr>
<tr>
<td>name</td>
<td>rule name</td>
</tr>
</tbody>
</table>

Supplement

- When `databaseName` is not specified, the default is the currently used DATABASE. If `DATABASE` is not used, `No database selected` will be prompted.

Example

- Query the rules for using the specified storage unit in specified database

```
SHOW RULES USED STORAGE UNIT ds_1 FROM sharding_db;
```

```
mysql> SHOW RULES USED STORAGE UNIT ds_1 FROM sharding_db;
+---------------------+------------+
| type                | name       |
+---------------------+------------+
| readwrite_splitting | ms_group_0 |
| readwrite_splitting | ms_group_0 |
+---------------------+------------+
2 rows in set (0.01 sec)
```

- Query the rules for using the specified storage unit in current database

```
SHOW RULES USED STORAGE UNIT ds_1;
```

```
mysql> SHOW RULES USED STORAGE UNIT ds_1;
+---------------------+------------+
| type                | name       |
+---------------------+------------+
2 rows in set (0.01 sec)

RUL Syntax

RUL (Resource Utility Language) responsible for SQL parsing, SQL formatting, preview execution plan and more utility functions.

PARSE SQL

Description

ThePARSE SQLsyntax is used to parse SQL and output abstract syntax tree.

Syntax

```
ParseSql ::= 
   'PARSE' sqlStatement
```

Return Value Description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parsed_statement</td>
<td>parsed SQL statement type</td>
</tr>
<tr>
<td>parsed_statement_detail</td>
<td>detail of the parsed statement</td>
</tr>
</tbody>
</table>
Apache ShardingSphere document

Example
• Parse SQL and output abstract syntax tree
PARSE SELECT * FROM t_order;

mysql> PARSE SELECT * FROM t_order;
+----------------------+----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------+
| parsed_statement

| parsed_statement_detail

|

Database Discovery

DB_DISCOVERY, TYPES, HEARTBEATS
This chapter will introduce how to use DistSQL to manage resources and rules in a distributed database.

Pre-work

Use MySQL as example, can replace to other databases.

1. Start the MySQL service;
2. Create to be registered MySQL databases;
3. Create role and user in MySQL with creation permission for ShardingSphere-Proxy;
4. Start Zookeeper service;

The above reserved words are not case-sensitive
5. Add mode and authentication configurations to server.yaml;
6. Start ShardingSphere-Proxy;
7. Use SDK or terminal connect to ShardingSphere-Proxy.

**Create Logic Database**

1. Create logic database

```sql
CREATE DATABASE foo_db;
```

2. Use newly created logic database

```sql
USE foo_db;
```

**Resource Operation**

More details please see concentrate rule examples.

**Rule Operation**

More details please see concentrate rule examples.

**Notice**

1. Currently, DROP DATABASE will only remove the logical distributed database, not the user’s actual database;
2. DROP TABLE will delete all logical fragmented tables and actual tables in the database;
3. CREATE DATABASE will only create a logical distributed database, so users need to create actual databases in advance.

**Sharding**

**Storage unit Operation**

- Configure data source information

```sql
REGISTER STORAGE UNIT ds_0 (  
    HOST = "127.0.0.1",  
    PORT = 3306,  
    DB = "ds_1",  
    USER = "root",  
    PASSWORD = "root"
)
```

Rule Operation

- Create sharding rule

```sql
CREATE SHARDING TABLE RULE t_order(
  STORAGE_UNITS(ds_0, ds_1),
  SHARDING_COLUMN=order_id,
  TYPE(NAME="hash_mod", PROPERTIES("sharding-count"="4"),
  KEY_GENERATE_STRATEGY(COLUMN=order_id, TYPE(NAME="snowflake"))
);
```

- Create sharding table

```sql
CREATE TABLE `t_order` (
  `order_id` int NOT NULL,
  `user_id` int NOT NULL,
  `status` varchar(45) DEFAULT NULL,
  PRIMARY KEY (`order_id`) ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4
```

- Drop sharding table

```sql
DROP TABLE t_order;
```

- Drop sharding rule

```sql
DROP SHARDING TABLE RULE t_order;
```

- Unregister storage unit

```sql
UNREGISTER STORAGE UNIT ds_0, ds_1;
```

- Drop distributed database

```sql
DROP DATABASE foo_db;
```
**ReadWrite_splitting**

**Storage unit Operation**

```sql
REGISTER STORAGE UNIT write_ds (  
    HOST="127.0.0.1",  
    PORT=3306,  
    DB="ds_0",  
    USER="root",  
    PASSWORD="root"  
), read_ds (  
    HOST="127.0.0.1",  
    PORT=3307,  
    DB="ds_0",  
    USER="root",  
    PASSWORD="root"  
);
```

**Rule Operation**

- Create `ReadWrite_splitting` rule

```sql
CREATE READWRITE_SPLITTING RULE group_0 (  
    WRITE_STORAGE_UNIT=write_ds,  
    READ_STORAGE_UNITS(read_ds),  
    TYPE(NAME="random")  
);
```

- Alter `ReadWrite_splitting` rule

```sql
ALTER READWRITE_SPLITTING RULE group_0 (  
    WRITE_STORAGE_UNIT=write_ds,  
    READ_STORAGE_UNITS(read_ds),  
    TYPE(NAME="random",PROPERTIES("read_weight"="2:0"))  
);
```

- Drop `ReadWrite_splitting` rule

```sql
DROP READWRITE_SPLITTING RULE group_0;
```

- Unregister storage unit

```sql
UNREGISTER STORAGE UNIT write_ds,read_ds;
```

- Drop distributed database
DROP DATABASE readwrite_splitting_db;

Encrypt

Storage unit Operation

REGISTER STORAGE UNIT ds_0 (HOST="127.0.0.1", PORT=3306, DB="ds_0", USER="root", PASSWORD="root");

Rule Operation

• Create encrypt rule

CREATE ENCRYPT RULE t_encrypt (COLUMNS(
  (NAME=user_id,CIPHER=user_cipher, ENCRYPT_ALGORITHM(TYPE(NAME='AES', PROPERTIES('aes-key-value'='123456abc'))),
  (NAME=order_id,CIPHER=order_cipher, ENCRYPT_ALGORITHM(TYPE(NAME='AES', PROPERTIES('aes-key-value'='123456abc'))))));

• Create encrypt table

CREATE TABLE `t_encrypt` (`id` int(11) NOT NULL, `user_id` varchar(45) DEFAULT NULL, `order_id` varchar(45) DEFAULT NULL, PRIMARY KEY (`id`)) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;

• Alter encrypt rule

ALTER ENCRYPT RULE t_encrypt (COLUMNS(
  (NAME=user_id,CIPHER=user_cipher, ENCRYPT_ALGORITHM(TYPE(NAME='AES', PROPERTIES('aes-key-value'='123456abc'))))));

• Drop encrypt rule
DROP ENCRYPT RULE t_encrypt;

• Unregister storage unit
UNREGISTER STORAGE UNIT ds_0;

• Drop distributed database
DROP DATABASE encrypt_db;

MASK

Storage unit Operation

REGISTER STORAGE UNIT ds_0 (HOST="127.0.0.1", PORT=3306, DB="ds_0", USER="root", PASSWORD="root");

Rule Operation

• Create mask rule
CREATE MASK RULE t_mask (COLUMNS(
  (NAME=phone_number, TYPE(NAME='MASK_FROM_X_TO_Y', PROPERTIES("from-x"=1, "to-y"=2, "replace-char"="*")),
  (NAME=address,TYPE(NAME='MD5'))));

• Create mask table
CREATE TABLE `t_mask` (`id` int(11) NOT NULL, `user_id` varchar(45) DEFAULT NULL, `phone_number` varchar(45) DEFAULT NULL, `address` varchar(45) DEFAULT NULL, PRIMARY KEY (`id`)) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;

• Alter mask rule
ALTER MASK RULE t_mask (COLUMNS((NAME=user_id, TYPE(NAME=’MD5’))));

• Drop mask rule

DROP MASK RULE t_mask;

• Unregister storage unit

UNREGISTER STORAGE UNIT ds_0;

• Drop distributed database

DROP DATABASE mask_db;

Shadow

Storage unit Operation

REGISTER STORAGE UNIT ds_0 (HOST=“127.0.0.1”, PORT=3306, DB=“ds_0”, USER=“root”, PASSWORD=“root”), ds_1 (HOST=“127.0.0.1”, PORT=3306, DB=“ds_1”, USER=“root”, PASSWORD=“root”), ds_2 (HOST=“127.0.0.1”, PORT=3306, DB=“ds_2”, USER=“root”, PASSWORD=“root”);
### Rule Operation

- **Create shadow rule**

```sql
CREATE SHADOW RULE group_0(
    SOURCE=ds_0,
    SHADOW=ds_1,
    t_order(TYPE(NAME="SQL_HINT"), TYPE(NAME="REGEX_MATCH", PROPERTIES("operation"= "insert", "column"="user_id", "regex"='[1]')),
    t_order_item(TYPE(NAME="SQL_HINT")));
```

- **Alter shadow rule**

```sql
ALTER SHADOW RULE group_0(
    SOURCE=ds_0,
    SHADOW=ds_2,
    t_order_item(TYPE(NAME="SQL_HINT")));
```

- **Drop shadow rule**

```sql
DROP SHADOW RULE group_0;
```

- **Unregister storage unit**

```sql
UNREGISTER STORAGE UNIT ds_0, ds_1, ds_2;
```

- **Drop distributed database**

```sql
DROP DATABASE foo_db;
```

### 9.2.4 Data Migration

#### Introduction

ShardingSphere provides solution of migrating data since **4.1.0**.

#### Build

#### Background

For systems running on a single database that urgently need to securely and simply migrate data to a horizontally sharded database.
Prerequisites

- Proxy is developed in JAVA, and JDK version 1.8 or later is recommended.
- Data migration adopts the cluster mode, and ZooKeeper is currently supported as the registry.

Procedure

1. Get ShardingSphere-Proxy. Please refer to proxy startup guide for details.
2. Modify the configuration file `conf/server.yaml`. Please refer to mode configuration for details.

Currently, mode must be Cluster, and the corresponding registry must be started in advance.

Configuration sample:

```yaml
mode:
  type: Cluster
repository:
  type: ZooKeeper
props:
  namespace: governance_ds
  server-lists: localhost:2181
  retryIntervalMilliseconds: 500
  timeToLiveSeconds: 60
  maxRetries: 3
  operationTimeoutMilliseconds: 500
```

3. Introduce JDBC driver.

Proxy has included JDBC driver of PostgreSQL and openGauss.

If the backend is connected to the following databases, download the corresponding JDBC driver jar package and put it into the `${shardingsphere-proxy}/ext-lib` directory.

<table>
<thead>
<tr>
<th>Database</th>
<th>JDBC Driver</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL</td>
<td>mysql-connector-java-8.0.31.jar</td>
</tr>
</tbody>
</table>

If you are migrating to a heterogeneous database, then you could use more types of database. Introduce JDBC driver as above too.

4. Start ShardingSphere-Proxy:

```
sh bin/start.sh
```

5. View the proxy log `logs/stdout.log`. If you see the following statements:

```
[INFO ] [main] o.a.s.p.frontend.ShardingSphereProxy - ShardingSphere-Proxy start success
```

9.2. ShardingSphere-Proxy
The startup will have been successful.

6. Configure and migrate on demand.

6.1. Query configuration.

```sql
SHOW MIGRATION RULE;
```

The default configuration is as follows.

| read | write |
| +-------------------------------------------------- | +-------------------------------------------------- |
| stream_channel | |
| +-------------------------------------------------- | +-------------------------------------------------- |
| {{"workerThread":20,"batchSize":1000,"shardingSize":10000000}} | {{"workerThread":20,"batchSize":1000}} | {{"type":"MEMORY","props":{"block-queue-size":"2000"}}} |

6.2. Alter configuration (Optional).

Since the migration rule has default values, there is no need to create it, only the ALTER statement is provided.

A completely configured DistSQL is as follows.

```sql
ALTER MIGRATION RULE (
READ(
    WORKER_THREAD=20,
    BATCH_SIZE=1000,
    SHARDING_SIZE=10000000,
    RATE_LIMITER (TYPE(NAME='QPS',PROPERTIES('qps='500')))
),
WRITE(
    WORKER_THREAD=20,
    BATCH_SIZE=1000,
    RATE_LIMITER (TYPE(NAME='TPS',PROPERTIES('tps='2000')))
),
STREAM_CHANNEL (TYPE(NAME='MEMORY',PROPERTIES('block-queue-size='2000')))
);```

Configuration item description:

```sql
ALTER MIGRATION RULE (READ(-- Data reading configuration. If it is not configured, part of the parameters will take effect by default.
    WORKER_THREAD=20, -- Obtain the thread pool size of all the data from the source side. If it is not configured, the default value is used.
    BATCH_SIZE=1000, -- The maximum number of records returned by a query operation.
```

9.2. ShardingSphere-Proxy 378
If it is not configured, the default value is used.

SHARDING_SIZE=10000000, -- Sharding size of all the data. If it is not configured, the default value is used.

RATE_LIMITER ( -- Traffic limit algorithm. If it is not configured, traffic is not limited.
  TYPE( -- Algorithm type. Option: QPS
  NAME='QPS',
  PROPERTIES( -- Algorithm property
  'qps'='500'
  )))
),

WRITE( -- Data writing configuration. If it is not configured, part of the parameters will take effect by default.
  WORKER_THREAD=20, -- The size of the thread pool on which data is written into the target side. If it is not configured, the default value is used.
  BATCH_SIZE=1000, -- The maximum number of records for a batch write operation. If it is not configured, the default value is used.
  RATE_LIMITER ( -- Traffic limit algorithm. If it is not configured, traffic is not limited.
  TYPE( -- Algorithm type. Option: TPS
  NAME='TPS',
  PROPERTIES( -- Algorithm property.
  'tps'='2000'
  )))
),

STREAM_CHANNEL ( -- Data channel. It connects producers and consumers, used for reading and writing procedures. If it is not configured, the MEMORY type is used by default.
  TYPE( -- Algorithm type. Option: MEMORY
  NAME='MEMORY',
  PROPERTIES( -- Algorithm property
  )))
);

DistSQL sample: configure READ for traffic limit.

ALTER MIGRATION RULE

READ

  RATE_LIMITER (TYPE(NAME='QPS',PROPERTIES('qps'='500'))) )
);

Configure data reading for traffic limit. Other configurations use default values.

6.3. Restore configuration.

To restore the default configuration, also through the ALTER statement.
ALTER MIGRATION RULE ( 
  READ(
    WORKER_THREAD=20,
    BATCH_SIZE=1000,
    SHARDING_SIZE=10000000,
    RATE_LIMITER (TYPE(NAME='QPS',PROPERTIES('qps'= '500'))) )
),
WRITE(
  WORKER_THREAD=20,
  BATCH_SIZE=1000,
  RATE_LIMITER (TYPE(NAME='TPS',PROPERTIES('tps'= '2000'))) )
),
STREAM_CHANNEL (TYPE(NAME='MEMORY',PROPERTIES('block-queue-size'= '200')));

Manual

MySQL user guide

Environment

Supported MySQL versions: 5.1.15 to 8.0.x.

Authority required

1. Enable binlog in source

MySQL 5.7 my.cnf configuration sample:

```
[mysqld]
server-id=1
log-bin=mysql-bin
binlog-format=row
binlog-row-image=full
max_connections=600
```

Run the following command and check whether binlog is enabled.

```
show variables like '%log_bin%';
show variables like '%binlog%';
```

If the following information is displayed, binlog is enabled.

```
+-----------------------------------------+---------------------------------------+
| Variable_name | Value          |                            |
+-----------------------------------------+---------------------------------------+
| log_bin      | ON             |
+-----------------------------------------+---------------------------------------+
```
2. Grant Replication-related permissions for source MySQL account.

Run the following command to check whether the user has migration permission.

```
SHOW GRANTS FOR 'migration_user';
```

Result sample:

```
+------------------------------------------------------------------------------+
| Grants for ${username}@${host}                                               |
+------------------------------------------------------------------------------+
| GRANT REPLICATION SLAVE, REPLICATION CLIENT ON *.* TO ${username}@${host}   |
|                  ........                                                |
+------------------------------------------------------------------------------+
```

3. Grant DDL DML permissions for MySQL account

Source MySQL account needs SELECT permission. Example:

```
GRANT SELECT ON migration_ds_0.* TO `migration_user`@`%`;
```

Target MySQL account needs part of DDL and all DML permissions. Example:

```
GRANT CREATE, DROP, INDEX, SELECT, INSERT, UPDATE, DELETE ON *.* TO `migration_  
user`@`%`;
```

Please refer to MySQL GRANT

**Complete procedure example**

**Requirements**

1. Prepare the source database, table, and data in MySQL.

```
DROP DATABASE IF EXISTS migration_ds_0;
CREATE DATABASE migration_ds_0 DEFAULT CHARSET utf8;

USE migration_ds_0

CREATE TABLE t_order (order_id INT NOT NULL, user_id INT NOT NULL, status  
VARCHAR(45) NULL, PRIMARY KEY (order_id));

INSERT INTO t_order (order_id, user_id, status) VALUES (1,2,'ok'),(2,4,'ok'),(3,6,  
'ok'),(4,1,'ok'),(5,3,'ok'),(6,5,'ok');
```
2. Prepare the target database in MySQL.

```sql
DROP DATABASE IF EXISTS migration_ds_10;
CREATE DATABASE migration_ds_10 DEFAULT CHARSET utf8;

DROP DATABASE IF EXISTS migration_ds_11;
CREATE DATABASE migration_ds_11 DEFAULT CHARSET utf8;

DROP DATABASE IF EXISTS migration_ds_12;
CREATE DATABASE migration_ds_12 DEFAULT CHARSET utf8;
```

Procedure

1. Create a new logical database in proxy and configure storage units and rules.

```sql
CREATE DATABASE sharding_db;

USE sharding_db

REGISTER STORAGE UNIT ds_2 (  
    URL="jdbc:mysql://127.0.0.1:3306/migration_ds_10?serverTimezone=UTC&useSSL=false",  
    USER="root",  
    PASSWORD="root",  
    PROPERTIES("minPoolSize"="1","maxPoolSize"="20","idleTimeout"="60000")
), ds_3 (  
    URL="jdbc:mysql://127.0.0.1:3306/migration_ds_11?serverTimezone=UTC&useSSL=false",  
    USER="root",  
    PASSWORD="root",  
    PROPERTIES("minPoolSize"="1","maxPoolSize"="20","idleTimeout"="60000")
), ds_4 (  
    URL="jdbc:mysql://127.0.0.1:3306/migration_ds_12?serverTimezone=UTC&useSSL=false",  
    USER="root",  
    PASSWORD="root",  
    PROPERTIES("minPoolSize"="1","maxPoolSize"="20","idleTimeout"="60000")
);

CREATE SHARDING TABLE RULE t_order(  
    STORAGE_UNITS(ds_2,ds_3,ds_4),  
    SHARDING_COLUMN=order_id,  
    TYPE(NAME="hash_mod",PROPERTIES("sharding-count"="6")),  
    KEY_GENERATE_STRATEGY(COLUMN=order_id,TYPE(NAME="snowflake"))
);
```

If you are migrating to a heterogeneous database, you need to execute the table-creation statements in proxy.
2. Configure the source storage units in proxy.

```sql
REGISTER MIGRATION SOURCE STORAGE UNIT ds_0 (  
    URL="jdbc:mysql://127.0.0.1:3306/migration_ds_0?serverTimezone=UTC&useSSL=false",  
    USER="root",  
    PASSWORD="root",  
    PROPERTIES("minPoolSize"="1","maxPoolSize"="20","idleTimeout"="60000")
);
```

3. Start data migration.

```sql
MIGRATE TABLE ds_0.t_order INTO t_order;
```

Or you can specify a target logical database.

```sql
MIGRATE TABLE ds_0.t_order INTO sharding_db.t_order;
```

4. Check the data migration job list.

```sql
SHOW MIGRATION LIST;
```

Result example:

```
+--------------------------------------------+--------------+----------------+-----  
| id            | tables         | job_item_count | active | create_time | stop_time |
+--------------------------------------------+--------------+----------------+-----  
| j0102p00002333dcb3d9db141cef14bed6fbf1ab54 | ds_0.t_order | 1             | true | 2023-09-20 14:41:32 | NULL |
+--------------------------------------------+--------------+----------------+-----  
```

5. View the data migration details.

```sql
SHOW MIGRATION STATUS 'j0102p00002333dcb3d9db141cef14bed6fbf1ab54';
```

Result example:

```
+-----------------------------+-------------+----------------+--------------------------+--------+----------  
| item | data_source | tables         | status         | active | processed_records_count | inventory_finished_percentage | incremental_idle_seconds | error_message |
|      |            |                |               |       |                      |                            |                        |              |
+-----------------------------+-------------+----------------+--------------------------+--------+----------  
```
6. Verify data consistency.

```
CHECK MIGRATION 'j0102p00002333dcb3d9db141cef14bed6fbf1ab54' BY TYPE (NAME='DATA_MATCH');
```

Data consistency check algorithm list:

```
SHOW MIGRATION CHECK ALGORITHMS;
```

Result example:

```
<table>
<thead>
<tr>
<th>type</th>
<th>type_aliases</th>
<th>supported_database_types</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CRC32_MATCH</td>
<td></td>
<td>MySQL,MariaDB,H2</td>
<td>Match CRC32 of records.</td>
</tr>
<tr>
<td>DATA_MATCH</td>
<td>[SQL92,MySQL,PostgreSQL,openGauss,Oracle,SQLServer, MariaDB,H2]</td>
<td>Match raw data of records.</td>
<td></td>
</tr>
</tbody>
</table>
```

If encrypt rule is configured in target proxy, then DATA_MATCH could be used.
If you are migrating to a heterogeneous database, then DATA_MATCH could be used.

Query data consistency check progress:

```
SHOW MIGRATION CHECK STATUS 'j0102p00002333dcb3d9db141cef14bed6fbf1ab54';
```

Result example:

```
<table>
<thead>
<tr>
<th>tables</th>
<th>result</th>
<th>check_failed_tables</th>
<th>active</th>
<th>inventory_finished_percentage</th>
<th>inventory_remaining_seconds</th>
<th>incremental_idle_seconds</th>
<th>check_begin_time</th>
<th>check_end_time</th>
<th>duration_seconds</th>
<th>algorithm_type</th>
<th>algorithm_props</th>
<th>error_message</th>
</tr>
</thead>
</table>
```
<table>
<thead>
<tr>
<th>ds_0.t_order</th>
<th>true</th>
<th>false</th>
<th>100</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td>2023-09-20 14:45:31.992</td>
<td>2023-09-20 14:45:33.519</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

7. Commit the job.

```sql
COMMIT MIGRATION 'j0102p00002333dcb3d9db141cef14bed6fbf1ab54';
```

Please refer to RAL#Migration for more details.

**PostgreSQL user guide**

**Environment**

Supported PostgreSQL version: 9.4 or later.

**Authority required**

1. Enable `test_decoding` in source.
2. Modify WAL configuration in source.

`postgresql.conf` configuration sample:

```
wal_level = logical
max_wal_senders = 10
max_replication_slots = 10
wal_sender_timeout = 0
max_connections = 600
```

Please refer to Write Ahead Log and Replication for details.

3. Grant replication permission for source PostgreSQL account.

`pg_hba.conf` instance configuration:

```
host replication repl_acct 0.0.0.0/0 md5
```

Please refer to The `pg_hba.conf` File for details.

4. Grant DDL DML permissions for PostgreSQL account.
If you are using a non-super admin account for migration, you need to GRANT CREATE and CONNECT privileges on the database used for migration.

```sql
GRANT CREATE, CONNECT ON DATABASE migration_ds_0 TO migration_user;
```

The account also needs to have access to the migrated tables and schema. Take the t_order table under test schema as an example.

```sql
\c migration_ds_0

GRANT USAGE ON SCHEMA test TO GROUP migration_user;
GRANT SELECT ON TABLE test.t_order TO migration_user;
```

PostgreSQL has the concept of OWNER, and if the account is the OWNER of a database, SCHEMA, or table, the relevant steps can be omitted.

Please refer to PostgreSQL GRANT

### Complete procedure example

#### Requirements

1. Prepare the source database, table, and data in PostgreSQL.

```sql
DROP DATABASE IF EXISTS migration_ds_0;
CREATE DATABASE migration_ds_0;

\c migration_ds_0

CREATE TABLE t_order (order_id INT NOT NULL, user_id INT NOT NULL, status VARCHAR(45) NULL, PRIMARY KEY (order_id));

INSERT INTO t_order (order_id, user_id, status) VALUES (1,2,'ok'),(2,4,'ok'),(3,6,'ok'),(4,1,'ok'),(5,3,'ok'),(6,5,'ok');
```

2. Prepare the target database in PostgreSQL.

```sql
DROP DATABASE IF EXISTS migration_ds_10;
CREATE DATABASE migration_ds_10;

DROP DATABASE IF EXISTS migration_ds_11;
CREATE DATABASE migration_ds_11;

DROP DATABASE IF EXISTS migration_ds_12;
CREATE DATABASE migration_ds_12;
```
Procedure

1. Create a new logical database in proxy and configure storage units and rules.

```sql
CREATE DATABASE sharding_db;
\c sharding_db

REGISTER STORAGE UNIT ds_2 (  
    URL="jdbc:postgresql://127.0.0.1:5432/migration_ds_10",  
    USER="postgres",  
    PASSWORD="root",  
    PROPERTIES("minPoolSize"="1","maxPoolSize"="20","idleTimeout"="60000")
), ds_3 (  
    URL="jdbc:postgresql://127.0.0.1:5432/migration_ds_11",  
    USER="postgres",  
    PASSWORD="root",  
    PROPERTIES("minPoolSize"="1","maxPoolSize"="20","idleTimeout"="60000")
), ds_4 (  
    URL="jdbc:postgresql://127.0.0.1:5432/migration_ds_12",  
    USER="postgres",  
    PASSWORD="root",  
    PROPERTIES("minPoolSize"="1","maxPoolSize"="20","idleTimeout"="60000")
);

CREATE SHARDING TABLE RULE t_order(  
    STORAGE_UNITS(ds_2,ds_3,ds_4),  
    SHARDING_COLUMN=order_id,  
    TYPE(NAME="hash_mod",PROPERTIES("sharding-count"="6")),  
    KEY_GENERATE_STRATEGY(COLUMN=order_id,TYPE(NAME="snowflake"))
);
```

If you are migrating to a heterogeneous database, you need to execute the table-creation statements in proxy.

2. Configure the source storage units in proxy.

```sql
REGISTER MIGRATION SOURCE STORAGE UNIT ds_0 (  
    URL="jdbc:postgresql://127.0.0.1:5432/migration_ds_0",  
    USER="postgres",  
    PASSWORD="root",  
    PROPERTIES("minPoolSize"="1","maxPoolSize"="20","idleTimeout"="60000")
);
```

3. Enable data migration.

```sql
MIGRATE TABLE ds_0.t_order INTO t_order;
```

Or you can specify a target logical database.
MIGRATE TABLE ds_0.t_order INTO sharding_db.t_order;

Or you can specify a source schema name.

MIGRATE TABLE ds_0.public.t_order INTO sharding_db.t_order;

4. Check the data migration job list.

SHOW MIGRATION LIST;

Result example:

+---------------------+------------+------------------+
| id                  | tables     | job_item_count   |
| active              | create_time| stop_time        |
+---------------------+------------+------------------+
| j0102p00002333dcb3d9db141cef14bed6fbf1ab54 | ds_0.t_order | 1 | true | 2023-09-20 14:41:32 | NULL |
+---------------------+------------+------------------+

5. View the data migration details.

SHOW MIGRATION STATUS 'j0102p00002333dcb3d9db141cef14bed6fbf1ab54';

Result example:

+------+-------------+--------------+--------------------------+--------+----------+
| item | data_source | tables       | status                   | active | processed_records_count | inventory_finished_percentage | incremental_idle_seconds | error_message |                |
+------+-------------+--------------+--------------------------+--------+--------------------------+--------------------------------+--------------------------+--------------+----------------+
| 0    | ds_0        | ds_0.t_order | EXECUTE_INCREMENTAL_TASK | true   | 100                      | 100                            |                           |              |                |
+------+-------------+--------------+--------------------------+--------+--------------------------+--------------------------------+--------------------------+--------------+----------------+

6. Verify data consistency.

CHECK MIGRATION 'j0102p00002333dcb3d9db141cef14bed6fbf1ab54';
Query OK, 0 rows affected (0.09 sec)
Query data consistency check progress:

```
SHOW MIGRATION CHECK STATUS 'j0102p00002333dcb3d9db141cef14bed6fbf1ab54';
```

Result example:

```
+--------------+--------+---------------------+--------+---------------------------+
<table>
<thead>
<tr>
<th>tables</th>
<th>result</th>
<th>check_failed_tables</th>
<th>active</th>
<th>inventory_finished_percentage</th>
<th>inventory_remaining_seconds</th>
<th>incremental_idle_seconds</th>
<th>check_begin_time</th>
<th>check_end_time</th>
<th>duration_seconds</th>
<th>algorithm_type</th>
<th>algorithm_props</th>
<th>error_message</th>
</tr>
</thead>
<tbody>
<tr>
<td>ds_0.t_order</td>
<td>true</td>
<td></td>
<td>false</td>
<td>100</td>
<td></td>
<td></td>
<td>2023-09-20 14:45:31.992</td>
<td>2023-09-20 14:45:33.519</td>
<td>2</td>
<td>DATA_MATCH</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

7. Commit the job.

```
COMMIT MIGRATION 'j0102p00002333dcb3d9db141cef14bed6fbf1ab54';
```

Please refer to RAL#Migration for more details.

**openGauss user guide**

**Environment**

Supported openGauss version: 2.0.1 to 3.0.0.

**Authority required**

1. Modify WAL configuration in source.

```
postgresql.conf configuration sample:

wal_level = logical
max_wal_senders = 10
max_replication_slots = 10
```

9.2. ShardingSphere-Proxy
wal_sender_timeout = 0
max_connections = 600

Please refer to Write Ahead Log and Replication for details.

2. Grant replication permission for source openGauss account.

pg_hba.conf instance configuration:

host replication repl_acct 0.0.0.0/0 md5

Please refer to Configuring Client Access Authentication and Example: Logic Replication Code for details.

3. Grant DDL DML permissions for openGauss account.

If you are using a non-super admin account for migration, you need to GRANT CREATE and CONNECT privileges on the database used for migration.

GRANT CREATE, CONNECT ON DATABASE migration_ds_0 TO migration_user;

The account also needs to have access to the migrated tables and schema. Take the t_order table under test schema as an example.

\c migration_ds_0

GRANT USAGE ON SCHEMA test TO GROUP migration_user;
GRANT SELECT ON TABLE test.t_order TO migration_user;

openGauss has the concept of OWNER, and if the account is the OWNER of a database, SCHEMA, or table, the relevant steps can be omitted.

openGauss does not allow normal accounts to operate in public schema, so if the migrated table is in public schema, you need to authorize additional.

Please refer to openGauss GRANT

GRANT ALL PRIVILEGES TO migration_user;

**Complete procedure example**

**Requirements**

1. Prepare the source database, table, and data.

1.1. Isomorphic database.

DROP DATABASE IF EXISTS migration_ds_0;
CREATE DATABASE migration_ds_0;
\c migration_ds_0
CREATE TABLE t_order (order_id INT NOT NULL, user_id INT NOT NULL, status VARCHAR(45) NULL, PRIMARY KEY (order_id));

INSERT INTO t_order (order_id, user_id, status) VALUES (1,2,'ok'),(2,4,'ok'),(3,6,'ok'),(4,1,'ok'),(5,3,'ok'),(6,5,'ok');

1.2. Heterogeneous database.

MySQL example:

DROP DATABASE IF EXISTS migration_ds_0;
CREATE DATABASE migration_ds_0 DEFAULT CHARSET utf8;

USE migration_ds_0

CREATE TABLE t_order (order_id INT NOT NULL, user_id INT NOT NULL, status VARCHAR(45) NULL, PRIMARY KEY (order_id));

INSERT INTO t_order (order_id, user_id, status) VALUES (1,2,'ok'),(2,4,'ok'),(3,6,'ok'),(4,1,'ok'),(5,3,'ok'),(6,5,'ok');

2. Prepare the target database in openGauss.

DROP DATABASE IF EXISTS migration_ds_10;
CREATE DATABASE migration_ds_10;

DROP DATABASE IF EXISTS migration_ds_11;
CREATE DATABASE migration_ds_11;

DROP DATABASE IF EXISTS migration_ds_12;
CREATE DATABASE migration_ds_12;

Procedure

1. Create a new logical database and configure storage units and rules.

1.1. Create logic database.

CREATE DATABASE sharding_db;
\c sharding_db;

1.2. Register storage units.

REGISTER STORAGE UNIT ds_2 (URL="jdbc:opengauss://127.0.0.1:5432/migration_ds_10", USER="gaussdb", PASSWORD="Root@123");
1.3. Create sharding table rule.

```
CREATE SHARDING TABLE RULE t_order(
    STORAGE_UNITS(ds_2, ds_3, ds_4),
    SHARDING_COLUMN=order_id,
    TYPE(NAME="hash_mod", PROPERTIES("sharding-count"="6")),
    KEY_GENERATE_STRATEGY(COLUMN=order_id, TYPE(NAME="snowflake"))
);
```

1.4. Create target table.

If you are migrating to a heterogeneous database, you need to execute the table-creation statements in proxy.

MySQL example:

```
CREATE TABLE t_order (order_id INT NOT NULL, user_id INT NOT NULL, status VARCHAR(45) NULL, PRIMARY KEY (order_id));
```

2. Configure the source storage units in proxy.

2.1. Isomorphic database.

```
REGISTER MIGRATION SOURCE STORAGE UNIT ds_0 (URL="jdbc:opengauss://127.0.0.1:5432/migration_ds_0",
    USER="gaussdb",
    PASSWORD="Root@123",
    PROPERTIES("minPoolSize"="1", "maxPoolSize"="20", "idleTimeout"="60000")
);
```

2.2. Heterogeneous database.

MySQL example:

```
REGISTER MIGRATION SOURCE STORAGE UNIT ds_0 (URL="jdbc:mysql://127.0.0.1:3306/migration_ds_0?serverTimezone=UTC&useSSL=false",
    USER="root",
    PASSWORD="Root@123",
    PROPERTIES("minPoolSize"="1", "maxPoolSize"="20", "idleTimeout"="60000")
);
```
3. Enable data migration.

MIGRATE TABLE ds_0.t_order INTO t_order;

Or you can specify a target logical database.

MIGRATE TABLE ds_0.t_order INTO sharding_db.t_order;

Or you can specify a source schema name.

MIGRATE TABLE ds_0.public.t_order INTO sharding_db.t_order;

4. Check the data migration job list.

SHOW MIGRATION LIST;

Result example:

<table>
<thead>
<tr>
<th>id</th>
<th>tables</th>
<th>job_item_count</th>
<th>active</th>
<th>create_time</th>
<th>stop_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>j0102p00002333dcb3d9db141cef14bed6f6bf1ab54</td>
<td>ds_0.t_order</td>
<td>1</td>
<td>true</td>
<td>2023-09-20 14:41:32</td>
<td>NULL</td>
</tr>
</tbody>
</table>

5. View the data migration details.

SHOW MIGRATION STATUS 'j0102p00002333dcb3d9db141cef14bed6f6bf1ab54';

Result example:

<table>
<thead>
<tr>
<th>item</th>
<th>data_source</th>
<th>tables</th>
<th>status</th>
<th>active</th>
<th>processed_records_count</th>
<th>inventory_finished_percentage</th>
<th>incremental_idle_seconds</th>
<th>error_message</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>ds_0</td>
<td>ds_0.t_order</td>
<td>EXECUTE_INCREMENTAL_TASK</td>
<td>true</td>
<td>180</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
6. Verify data consistency.

```
CHECK MIGRATION 'j0102p00002333dcb3d9db141cef14bed6fbf1ab54';
Query OK, 0 rows affected (0.09 sec)
```

Query data consistency check progress:

```
SHOW MIGRATION CHECK STATUS 'j0102p00002333dcb3d9db141cef14bed6fbf1ab54';
```

Result example:

```
| tables | result | check_failed_tables | active | inventory_finished_percentage | inventory_remaining_seconds | incremental_idle_seconds | check_begin_time | check_end_time | duration_seconds | algorithm_type | algorithm_props | error_message |
|--------+--------+---------------------+--------+---------------------+--------------------------+----------------+-----------------+---------------+-----------------+----------------+-----------------------------+----------------|
| ds_0.t_order | true | | false | 100 | | | 2023-09-20 14:45:31.992 | 2023-09-20 14:45:33.519 | 2 | DATA_MATCH |
```

7. Commit the job.

```
COMMIT MIGRATION 'j0102p00002333dcb3d9db141cef14bed6fbf1ab54';
```

Please refer to RAL#Migration for more details.
9.2.5 Observability

Agent

Compile source code

Download Apache ShardingSphere from GitHub, then compile.

```bash
git clone --depth 1 https://github.com/apache/shardingsphere.git
cd shardingsphere
mvn clean install -DskipITs -DskipTests -Prelease
```

Artifact is `distribution/agent/target/apache-shardingsphere-${latest.release.version}-shardingsphere-agent-bin.tar.gz`

Directory structure

Create agent directory, and unzip agent distribution package to the directory.

```bash
mkdir agent
tar -zxvf apache-shardingsphere-${latest.release.version}-shardingsphere-agent-bin.tar.gz -C agent
cd agent
tree
├── LICENSE
├── NOTICE
├── conf
│   └── agent.yaml
├── plugins
│   ├── lib
│   │   ├── shardingsphere-agent-metrics-core-${latest.release.version}.jar
│   │   └── shardingsphere-agent-plugin-core-${latest.release.version}.jar
│   └── logging
│       └── shardingsphere-agent-logging-file-${latest.release.version}.jar
└── shardingsphere-agent-${latest.release.version}.jar
```

Agent log output location is `agent/logs/stdout.log`.
**Configuration**

`conf/agent.yaml` is used to manage agent configuration. Built-in plugins include File, Prometheus, OpenTelemetry.

```yaml
plugins:
  # logging:
  #   File:
  #     props:
  #       level: "INFO"
  # metrics:
  #   Prometheus:
  #     host: "localhost"
  #     port: 9090
  #     props:
  #       jvm-information-collector-enabled: "true"
  # tracing:
  #   OpenTelemetry:
  #     props:
  #       otel.service.name: "shardingsphere"
  #       otel.traces.exporter: "jaeger"
  #       otel.exporter.otlp.traces.endpoint: "http://localhost:14250"
  #       otel.traces.sampler: "always_on"
```

**Plugin description**

**File**

Currently, the File plugin only outputs the time-consuming log output of building metadata, and has no other log output for the time being.

**Prometheus**

Used for exposure monitoring metrics.

- Parameter description

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>host IP</td>
</tr>
<tr>
<td>port</td>
<td>port</td>
</tr>
<tr>
<td>jvm-information-collector-enabled</td>
<td>whether to collect JVM indicator information</td>
</tr>
</tbody>
</table>
OpenTelemetry

OpenTelemetry can export tracing data to Jaeger, Zipkin.

- Parameter description

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>otel.service.name</td>
<td>service name</td>
</tr>
<tr>
<td>otel.traces.exporter</td>
<td>traces exporter</td>
</tr>
<tr>
<td>otel.exporter.otlp.traces.endpoint</td>
<td>traces endpoint</td>
</tr>
<tr>
<td>otel.traces.sampler</td>
<td>traces sampler</td>
</tr>
</tbody>
</table>

Parameter reference [OpenTelemetry SDK Autoconfigure](#)

Usage in ShardingSphere-Proxy

Using via a non-container environment

- Edit the startup script

Configure the absolute path of shardingsphere-agent-${latest.release.version}.jar to the start.sh startup script of shardingsphere proxy.

```
nohup java ${JAVA_OPTS} ${JAVA_MEM_OPTS} \ 
-javaagent:/xxxxx/agent/shardingsphere-agent-${latest.release.version}.jar \ 
-classpath ${CLASS_PATH} ${MAIN_CLASS} >> ${STDOUT_FILE} 2>&1 &
```

- Start ShardingSphere-Proxy

`bin/start.sh`

After startup, you can find the plugin info in the log of ShardingSphere-Proxy, Metric and Tracing data can be viewed through the configured monitoring address.

Use via container environment

- Assume that the following corresponding configurations have been completed locally.
  - Folder `./custom/agent/` that contains all files after unpacking ShardingSphere-Agent binary package
  - The folder containing the configuration files of ShardingSphere-Proxy such as `server.yaml` is `./custom/conf/`
- At this point, the use of ShardingSphere-Agent can be configured through the environment variable `JVM_OPT`. Taking starting in the Docker Compose environment as an example, a reasonable `docker-compose.yml` example is as follows.
version: "3.8"

services:
apache-shardingsphere-proxy:
  image: apache/shardingsphere-proxy:latest
  environment:
    JVM_OPTS: "-javaagent:/agent/shardingsphere-agent-${latest.release.version}.jar"
  PORT: 3308
  volumes:
    - ./custom/agent:/agent/
    - ./custom/conf:/opt/shardingsphere-proxy/conf/
  ports:
    - "13308:3308"

## Metrics

<table>

</table>
### 9.2.6 Optional Plugins

ShardingSphere only includes the implementation of the core SPI by default, and there is a part of the SPI that contains third-party dependencies in Git Source Implemented plugins are not included. **Retrievable at** [https://central.sonatype.com/](https://central.sonatype.com/).

All the built-in plugins for ShardingSphere-Proxy are listed below in the form of ‘groupId:artifactId’:

- org.apache.shardingsphere:shardingsphere-cluster-mode-repository-etcd, etcd implementation of persistent definition of cluster mode configuration information
- org.apache.shardingsphere:shardingsphere-cluster-mode-repository-zookeeper, the zookeeper implementation of the persistent definition of cluster mode configuration information
- org.apache.shardingsphere:shardingsphere-jdbc-core, JDBC core
- org.apache.shardingsphere:shardingsphere-db-protocol-core, database protocol core
- org.apache.shardingsphere:shardingsphere-mysql-protocol, the MySQL implementation of the database protocol
- org.apache.shardingsphere:shardingsphere-postgresql-protocol, the PostgreSQL implementation of the database protocol
- org.apache.shardingsphere:shardingsphere-opengauss-protocol, the OpenGauss implementation of the database protocol
- org.apache.shardingsphere:shardingsphere-proxy-frontend-core, used by ShardingSphere-Proxy to parse and adapt the protocol for accessing the database
- org.apache.shardingsphere:shardingsphere-proxy-frontend-mysql, a MySQL implementation for ShardingSphere-Proxy to parse and adapt the protocol for accessing the database
- org.apache.shardingsphere:shardingsphere-proxy-frontend-postgresql, a PostgreSQL implementation for ShardingSphere-Proxy to parse and adapt the protocol for accessing the database
- org.apache.shardingsphere:shardingsphere-proxy-frontend-opengauss, an openGauss implementation for ShardingSphere-Proxy to parse and adapt the protocol for accessing the database
- org.apache.shardingsphere:shardingsphere-proxy-backend-core, the backend core for ShardingSphere Proxy
- org.apache.shardingsphere:shardingsphere-standalone-mode-core, the persistence definition core of single-machine mode configuration information

For the core org.apache.shardingsphere:shardingsphere-jdbc-core, its built-in plugins reference ShardingSphere-JDBC Optional Plugins.
If ShardingSphere Proxy needs to use optional plugins, you need to download the JAR containing its SPI implementation and its dependent JARs from Maven Central.

All optional plugins are listed below in the form of groupId:artifactId.

- Standalone mode configuration information persistence definition
  - org.apache.shardingsphere:shardingsphere-standalone-mode-repository-jdbc, JDBC based persistence

- Cluster mode configuration information persistence definition
  - org.apache.shardingsphere:shardingsphere-cluster-mode-repository-consul, Consul based persistence

- XA transaction manager provider definition
  - org.apache.shardingsphere:shardingsphere-transaction-xa-narayana, XA distributed transaction manager based on Narayana

- SQL translator
  - org.apache.shardingsphere:shardingsphere-sql-translator-jooq-provider, JooQ SQL translator

- Row Value Expressions definition
  - org.apache.shardingsphere:shardingsphere-infra-expr-espresso, Row Value Expressions that uses the Groovy syntax based on GraalVM Truffle’s Espresso implementation

- Database type identification
  - org.apache.shardingsphere:shardingsphere-infra-database-testcontainers, Adaptation of jdbcURL for JDBC support of testcontainers-java

In addition to the above optional plugins, ShardingSphere community developers have contributed a number of plugin implementations. These plugins can be found in ShardingSphere Plugins repository. Plugins in ShardingSphere Plugin repository would remain the same release plan with ShardingSphere, they can be retrieved at https://central.sonatype.com/, and install into ShardingSphere.

### 9.2.7 Session Management

ShardingSphere supports session management. You can view the current session or kill the session through the SQL of the native database. At present, this function is only available when the storage node is MySQL. MySQL SHOW PROCESSLIST and KILL commands are supported.
Usage

View Session

Different methods of viewing sessions are supported for different associated databases. The `SHOW PROCESSLIST` command can be used to view sessions for associated MySQL databases. ShardingSphere will automatically generate a unique UUID ID as the ID, and store the SQL execution information in each instance. When this command is executed, ShardingSphere will collect and synchronize the SQL execution information of each computing node through the governance center, and then summarize and return it to the user.

```
mysql> show processlist;
+-----------------+----------------+---------+-----------------+---------+---+
| Id              | User           | Host    | db               | Command | Time |
+-----------------+----------------+---------+-----------------+---------+---+
| 05ede3bd584fd4a429dcaac382be2973 | root           | 127.0.0.1 | sharding_db      | Execute | 2   |
|                 |                |         |                 |         |     |
| f9e5c97431567415fe10bdc5fa46378 | root           | 127.0.0.1 | sharding_db      | Sleep   | 690 |
|                 |                |         |                 |         |     |
```

• Output Description

Simulates the output of native MySQL, but the Id field is a special random string.

Kill Session

The user determines whether the KILL statement needs to be executed according to the results returned by `SHOW PROCESSLIST`. ShardingSphere cancels the SQL being executed according to the ID in the KILL statement.

```
mysql> kill 05ede3bd584fd4a429dcaac382be2973;
Query OK, 0 rows affected (0.04 sec)

mysql> show processlist;
Empty set (0.02 sec)
```
9.2.8 Logging Configuration

Background

ShardingSphere uses Logback for log management, and the Java SPI internally to provide default log configuration. Users can use XML files to configure customized log output. Proxy will preferentially read the log configuration provided in logback.xml in the /conf directory.

The following steps describe how to customize the log configuration.

Procedure

1. Create file conf/logback.xml

Customize the logger level and pattern, etc. according to your needs. It is recommended to make modifications based on the configuration example.

2. View logs

After ShardingSphere-Proxy starts, the log will be output to the logs directory, select the target log file to view.

Sample

```xml
<?xml version="1.0"?>
<!--
   Licensed to the Apache Software Foundation (ASF) under one or more contributor license agreements. See the NOTICE file distributed with this work for additional information regarding copyright ownership.
   The ASF licenses this file to You under the Apache License, Version 2.0 (the "License"); you may not use this file except in compliance with the License. You may obtain a copy of the License at
   http://www.apache.org/licenses/LICENSE-2.0
   Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied. See the License for the specific language governing permissions and limitations under the License.
-->

<configuration>
  <appender name="console" class="ch.qos.logback.core.ConsoleAppender">
    <encoder>
      <pattern>[%-5level] [%d{yyyy-MM-dd HH:mm:ss.SSS}] [%thread] [%logger{36} - %msg%n</pattern>
    </encoder>
  </appender>
</configuration>
```
9.2.9 CDC

CDC (Change Data Capture) captures incremental data changes. CDC can monitor data changes in the storage nodes of ShardingSphere-Proxy, capture data operation events, filter and extract useful information, and finally send these changed data to a specified target.

CDC can be used for data synchronization, data backup and recovery, it currently supports openGauss, MySQL, and PostgreSQL.

Build

Background Information

ShardingSphere CDC is divided into two parts, one is the CDC Server, and the other is the CDC Client. The CDC Server and ShardingSphere-Proxy are currently deployed together.

Users can introduce the CDC Client into their own projects to implement data consumption logic.

Constraints

- Pure JAVA development, JDK recommended 1.8 or above.
- CDC Server requires ShardingSphere-Proxy to use cluster mode, currently supports ZooKeeper as the registry center.
- CDC only synchronizes data, does not synchronize table structure, and currently does not support DDL statement synchronization.
- CDC incremental task will not split transaction data of the database shards. If you want to enable XA transaction compatibility, both openGauss and ShardingSphere-Proxy need the GLT module.
**CDC Server Deployment Steps**

Here, the openGauss database is used as an example to introduce the deployment steps of the CDC Server.

Since the CDC Server is built into ShardingSphere-Proxy, you need to get ShardingSphere-Proxy. For details, please refer to the proxy startup manual.

**Configure GLT Module (Optional)**

The official website’s released binary package does not include the GLT module by default, if you are using the openGauss database with GLT functionality, you can additionally introduce the GLT module to ensure the integrity of XA transactions.

There are currently two ways to introduce the GLT module, and corresponding configurations need to be made in server.yaml.

1. **Source code compilation and installation**

1.1 Prepare the code environment, download in advance or use Git clone to download the ShardingSphere source code from Github.

1.2 Delete the `<scope>provided</scope>` tag of the shardingsphere-global-clock-tso-provider-redis dependency in kernel/global-clock/type/tso/core/pom.xml and the `<scope>provided</scope>` tag of jedis in kernel/global-clock/type/tso/provider/redis/pom.xml

1.3 Compile ShardingSphere-Proxy, for specific compilation steps, please refer to the ShardingSphere Compilation Manual.

2. **Directly introduce GLT dependencies**

Can be introduced from the maven repository

2.1. `shardingsphere-global-clock-tso-provider-redis`, download the same version as ShardingSphere-Proxy

2.2. `jedis-4.3.1`

**CDC Server User Manual**

1. Modify the configuration file `conf/server.yaml` and turn on the CDC function. Currently, mode must be Cluster, and the corresponding registry center needs to be started in advance. If the GLT provider uses Redis, Redis needs to be started in advance.

Configuration example:

1. Enable CDC function in `server.yaml`. 
mode:
  type: Cluster
repository:
  type: ZooKeeper
props:
  namespace: cdc_demo
  server-lists: localhost:2181
  retryIntervalMilliseconds: 500
  timeToLiveSeconds: 60
  maxRetries: 3
  operationTimeoutMilliseconds: 500

authority:
  users:
    - user: root@%
      password: root
  privilege:
    type: ALL_PERMITTED

# When using GLT, you also need to enable distributed transactions, GLT is only supported by the openGauss database currently.
#transaction:
#  defaultType: XA
#  providerType: Atomikos
#
#globalClock:
#  enabled: true
#  type: TSO
#  provider: redis
#  props:
#    host: 127.0.0.1
#    port: 6379

props:
  system-log-level: INFO
  proxy-default-port: 3307 # Proxy default port.
  cdc-server-port: 33071 # CDC Server port, must be configured
  proxy-frontend-database-protocol-type: openGauss # Consistent with the type of backend database

2. Introduce JDBC driver.

Proxy has included JDBC driver of PostgreSQL and openGauss.

If the backend is connected to the following databases, download the corresponding JDBC driver jar package and put it into the `${shardingsphere-proxy}/ext-lib` directory.

<table>
<thead>
<tr>
<th>Database</th>
<th>JDBC Driver</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL</td>
<td>mysql-connector-java-8.0.31.jar</td>
</tr>
</tbody>
</table>
4. Start ShardingSphere-Proxy:

```
sh bin/start.sh
```

5. View the proxy log logs/stdout.log. If you see the following statements:

```
[INFO ] [main] o.a.s.p.frontend.ShardingSphereProxy - ShardingSphere-Proxy Cluster mode started successfully
```

The startup will have been successful.

6. Configure CDC on demand.

6.1. Query configuration.

```
SHOW STREAMING RULE;
```

The default configuration is as follows:

```
+--------------------------------------------------------------+-------------------+-------------------------------------------------------+
| read | write |
| stream_channel | |
+--------------------------------------------------------------+-------------------+-------------------------------------------------------+
|  | |
| +--------------------------------------------------------------+-------------------+-------------------------------------------------------+
| read |write |
| +--------------------------------------------------------------+-------------------+-------------------------------------------------------+
| | |
| +--------------------------------------------------------------+-------------------+-------------------------------------------------------+
| | |
| +--------------------------------------------------------------+-------------------+-------------------------------------------------------+
| | |
| +--------------------------------------------------------------+-------------------+-------------------------------------------------------+

6.2. Alter configuration (optional).

Since the streaming rule has default values, there is no need to create it, only the ALTER statement is provided.

A completely configured DistSQL is as follows.

```
ALTER STREAMING RULE(
  
READ(
    WORKER_THREAD=20,
    BATCH_SIZE=1000,
    SHARDING_SIZE=10000000,
    RATE_LIMITER (TYPE(NAME='QPS',PROPERTIES('qps'=1500)) )
  ),
  
WRITE(
    WORKER_THREAD=20,
    BATCH_SIZE=1000,
    RATE_LIMITER (TYPE(NAME='TPS',PROPERTIES('tps'=2000)) )
  ),
  
STREAM_CHANNEL (TYPE(NAME='MEMORY',PROPERTIES('block-queue-size'=2000)) )
);
```
Configuration item description:

```sql
ALTER STREAMING RULE (  
READ( -- Data reading configuration. If it is not configured, part of the  
parameters will take effect by default.  
   WORKER_THREAD=20, -- Affects full and incremental tasks, obtain the thread pool  
size of all the data from the source side. If it is not configured, the default  
value is used. It needs to ensure that this value is not lower than the number of  
database shards.  
   BATCH_SIZE=1000, -- Affects full and incremental tasks, the maximum number of  
records returned by a query operation. If it is not configured, the default value  
is used. If the amount of data in a transaction is greater than this value, the  
incremental situation may exceed the set value.  
   SHARDING_SIZE=10000000, -- Affects full tasks, sharding size of all the data. If  
it is not configured, the default value is used.  
   RATE_LIMITER ( -- Affects full and incremental tasks, traffic limit algorithm. If  
it is not configured, traffic is not limited.  
      TYPE( -- Algorithm type. Option: QPS  
         NAME='QPS',  
         PROPERTIES( -- Algorithm property  
            'qps'='500'  
         )  
      )  
   ),  
WRITE( -- Data writing configuration. If it is not configured, part of the  
parameters will take effect by default.  
   WORKER_THREAD=20, -- Affects full and incremental tasks, the size of the thread  
pool on which data is written into the target side. If it is not configured, the  
default value is used.  
   BATCH_SIZE=1000, -- Affects full and incremental tasks, the maximum number of  
records for a batch write operation. If it is not configured, the default value is  
used. If the amount of data in a transaction is greater than this value, the  
incremental situation may exceed the set value.  
   RATE_LIMITER ( -- Traffic limit algorithm. If it is not configured, traffic is  
not limited.  
      TYPE( -- Algorithm type. Option: TPS  
         NAME='TPS',  
         PROPERTIES( -- Algorithm property  
            'tps'='2000'  
         )  
      )  
   ),  
STREAM_CHANNEL ( -- Data channel. It connects producers and consumers, used for  
reading and writing procedures. If it is not configured, the MEMORY type is used by  
default.  
      TYPE( -- Algorithm type. Option: MEMORY  
         NAME='MEMORY',  
         PROPERTIES( -- Algorithm property  
         )  
      ));
```

9.2. ShardingSphere-Proxy
The CDC Client does not need to be deployed separately, just need to introduce the dependency of the CDC Client through maven to use it in the project. Users can interact with the server through the CDC Client.

If necessary, users can also implement a CDC Client themselves to consume data and ACK.

```xml
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-data-pipeline-cdc-client</artifactId>
  <version>${version}</version>
</dependency>
```

**CDC Client Introduction**

`org.apache.shardingsphere.data.pipeline.cdc.client.CDCClient` is the entry class of the CDC Client. Users can interact with the CDC Server through this class. The main new methods are as follows.

<table>
<thead>
<tr>
<th>Method Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connect(Consumer&lt;List&gt; dataConsumer, ExceptionHandler exceptionHandler, ServerErrorResultHandler errorResultHandler)</td>
<td>void</td>
<td>Connect with the server, when connecting, you need to specify 1. Data consumption processing function 2. Exception handling logic during consumption 3. Server error exception handling function</td>
</tr>
<tr>
<td>login(CDCLoginParameter parameter)</td>
<td>void</td>
<td>CDC login, parameters username: username password: password</td>
</tr>
<tr>
<td>startStreaming(StartStreamingParameter parameter)</td>
<td>String</td>
<td>Start CDC subscription StartStreamingParameter parameters database: logical database name schemaTables: subscribed table name full: whether to subscribe to full data</td>
</tr>
<tr>
<td>restartStreaming(String streamingId)</td>
<td>void</td>
<td>Restart subscription</td>
</tr>
<tr>
<td>stopStreaming(String streamingId)</td>
<td>void</td>
<td>Stop subscription</td>
</tr>
<tr>
<td>dropStreaming(String streamingId)</td>
<td>void</td>
<td>Delete subscription</td>
</tr>
<tr>
<td>await()</td>
<td>void</td>
<td>Block the CDC thread and wait for the channel to close</td>
</tr>
<tr>
<td>close()</td>
<td>void</td>
<td>Close the channel, the process ends</td>
</tr>
</tbody>
</table>
Manual

Introduction to CDC Function

CDC only synchronizes data, it does not synchronize table structures, and currently does not support the synchronization of DDL statements.

Introduction to CDC Protocol

The CDC protocol uses Protobuf, and the corresponding Protobuf types are mapped based on the types in Java.

Here, taking openGauss as an example, the mapping relationship between the data types of the CDC protocol and the database types is as follows.
<table>
<thead>
<tr>
<th>openGauss type</th>
<th>Java data type</th>
<th>CDC corresponding protobuf type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>tinyint, smallint, integer</td>
<td>Integer</td>
<td>int32</td>
<td></td>
</tr>
<tr>
<td>bigint</td>
<td>Long</td>
<td>int64</td>
<td></td>
</tr>
<tr>
<td>numeric</td>
<td>Big Decimal</td>
<td>string</td>
<td></td>
</tr>
<tr>
<td>real, float4</td>
<td>Float</td>
<td>float</td>
<td></td>
</tr>
<tr>
<td>binary_double, double precision</td>
<td>Double</td>
<td>double</td>
<td></td>
</tr>
<tr>
<td>boolean</td>
<td>Boolean</td>
<td>bool</td>
<td></td>
</tr>
<tr>
<td>char, varchar, text, clob</td>
<td>String</td>
<td>string</td>
<td></td>
</tr>

</table>
Environmental Requirements

Supported openGauss versions: 2.x ~ 3.x.

Permission Requirements

1. Adjust the source end WAL configuration.

Example configuration for postgresql.conf:

```
wal_level = logical
max_wal_senders = 10
max_replication_slots = 10
wal_sender_timeout = 0
max_connections = 600
```

For details, please refer to Write Ahead Log and Replication.

2. Grant replication permission to the source end openGauss account.

Example configuration for pg_hba.conf:

```
host replication repl_acct 0.0.0.0/0 md5
# 0.0.0.0/0 means allowing access from any IP address, which can be adjusted to the IP address of the CDC Server according to the actual situation
```

For details, please refer to Configuring Client Access Authentication and Example: Logic Replication Code.

3. Grant DDL DML permissions to the openGauss account.

If a non-super administrator account is used, it is required that this account has CREATE and CONNECT permissions on the database used.

Example:

```
GRANT CREATE, CONNECT ON DATABASE source_ds TO cdc_user;
```

The account also needs to have access permissions to the table and schema to be subscribed, taking the t_order table under the test schema as an example.

```
\c source_ds
GRANT USAGE ON SCHEMA test TO GROUP cdc_user;
GRANT SELECT ON TABLE test.t_order TO cdc_user;
```

openGauss has the concept of OWNER. If it is the OWNER of the database, SCHEMA, or table, the corresponding authorization steps can be omitted.
openGauss does not allow ordinary accounts to operate under the public schema. So if the table to be migrated is under the public schema, additional authorization is needed.

```sql
GRANT ALL PRIVILEGES TO cdc_user;
```

For details, please refer to openGauss GRANT

### Complete Process Example

#### Prerequisites

1. Prepare the database, table, and data of the CDC source end.

```sql
DROP DATABASE IF EXISTS ds_0;
CREATE DATABASE ds_0;

DROP DATABASE IF EXISTS ds_1;
CREATE DATABASE ds_1;
```

#### Configure CDC Server

1. Create a logical database.

```sql
CREATE DATABASE sharding_db;
\c sharding_db
```

2. Register storage unit.

```sql
REGISTER STORAGE UNIT ds_0 (  
    URL="jdbc:opengauss://127.0.0.1:5432/ds_0",  
    USER="gaussdb",  
    PASSWORD="Root@123",  
    PROPERTIES("minPoolSize"="1","maxPoolSize"="20","idleTimeout"="60000")
  ), ds_1 (  
    URL="jdbc:opengauss://127.0.0.1:5432/ds_1",  
    USER="gaussdb",  
    PASSWORD="Root@123",  
    PROPERTIES("minPoolSize"="1","maxPoolSize"="20","idleTimeout"="60000")
  );
```

3. Create sharding rules.

```sql
CREATE SHARDING TABLE RULE t_order(  
STORAGE_UNITS(ds_0,ds_1),  
SHARDING_COLUMN=order_id,  
TYPE(NAME="hash_mod",PROPERTIES("sharding-count"="2")),
```
4. Create tables

Execute the creation table statement in the proxy.

```sql
CREATE TABLE t_order (order_id INT NOT NULL, user_id INT NOT NULL, status VARCHAR(45) NULL, PRIMARY KEY (order_id));
```

Start CDC Client

Currently, the CDC Client only provides a Java API, and users need to implement the data consumption themselves.

Below is a simple example of starting the CDC Client.

```java
import lombok.SneakyThrows;
import lombok.extern.slf4j.Slf4j;
import org.apache.shardingsphere.data.pipeline.cdc.client.CDCClient;
import org.apache.shardingsphere.data.pipeline.cdc.client.config.CDCClientConfiguration;
import org.apache.shardingsphere.data.pipeline.cdc.client.handler.RetryStreamingExceptionHandler;
import org.apache.shardingsphere.data.pipeline.cdc.client.parameter.CDCLoginParameter;
import org.apache.shardingsphere.data.pipeline.cdc.client.parameter.StartStreamingParameter;
import org.apache.shardingsphere.data.pipeline.cdc.protocol.request.StreamDataRequestBody.SchemaTable;
import java.util.Collections;

@Slf4j
public final class Bootstrap {

    @SneakyThrows(InterruptedException.class)
    public static void main(final String[] args) {
        String address = "127.0.0.1";
        // Construct CDCClient, pass in CDCClientConfiguration, CDCClientConfiguration contains the address and port of the CDC Server, as well as the timeout time
        try (CDCClient cdcClient = new CDCClient(new CDCClientConfiguration(address, 33071, 10000))) {
            // First call connect to the CDC Server, you need to pass in 1. Data consumption processing logic 2. Exception handling logic during consumption 3. Server error exception handling logic
            cdcClient.connect(records -> log.info("records: {}", records), new
```
There are mainly 4 steps. 1. Construct CDCClient, pass in CDCClientConfiguration. 2. Call CDCClient.connect(), this step is to establish a connection with the CDC Server. 3. Call CDCClient.login(), log in with the username and password configured in server.yaml. 4. Call CDCClient.startStreaming(), start subscribing, you need to ensure that the subscribed database and table exist in ShardingSphere-Proxy, otherwise an error will be reported.

CDCClient.await is to block the main thread, it is not a necessary step, other methods can also be used, as long as the CDC thread is always working.

If you need more complex data consumption implementation, such as writing to the database, you can refer to DataSourceRecordConsumer

### Write Data

When write data through a proxy, the CDC Client is notified of the data change.

```
INSERT INTO t_order (order_id, user_id, status) VALUES (1,1,'ok1'),(2,2,'ok2'),(3,3,'ok3');
UPDATE t_order SET status='updated' WHERE order_id = 1;
DELETE FROM t_order WHERE order_id = 2;
```

Bootstrap will output a similar log.

```
records: [before {
  name: "order_id"
  value {
    type_url: "type.googleapis.com/google.protobuf.Empty"
  }
  .......
}]
```
**View the Running Status of the CDC Task**

The start and stop of the CDC task can only be controlled by the CDC Client. You can view the status of the CDC task by executing DistSQL in the proxy.

1. View the CDC task list

   **SHOW STREAMING LIST;**

   Running result

   ```
   sharding_db=> SHOW STREAMING LIST;
   id | database | tables | job_item_count | active | create_time | stop_time
   +---------------------+-------------+---------+---------------+--------+-------------+-----------
   j0302p0000702a83116fcee83f70419ca5e2993791 | sharding_db | t_order | 1            | true   | 2023-10-27 22:01:27 |
   (1 row)
   ```

2. View the details of the CDC task

   **SHOW STREAMING STATUS j0302p0000702a83116fcee83f70419ca5e2993791;**

   Running result

   ```
   sharding_db=> SHOW STREAMING STATUS j0302p0000702a83116fcee83f70419ca5e2993791;
   item | data_source | status | active | processed_records_count | inventory_finished_percentage | incremental_idle_seconds | confirmed_position | current_position | error_message
   +-------------------------------+--------------------------+--------+-------------------------+-------------------------------+--------------------------+-------------------+-------------------+-------------------+-------------------
   0 | ds_0 | EXECUTE_INCREMENTAL_TASK | false | 2                      | 100                         | 5/597E43D0             | 5/597E4810        |                   |                   |
   1 | ds_1 | EXECUTE_INCREMENTAL_TASK | false | 3                      |                              |                       |                   |                   |                   |
   (2 rows)
   ```

3. Drop CDC task

   **DROP STREAMING j0302p0000702a83116fcee83f70419ca5e2993791;**

   The CDC task can only be deleted when there are no subscriptions. At this time, the replication slots on the openGauss physical database will also be deleted.

   ```
   sharding_db=> DROP STREAMING j0302p0000702a83116fcee83f70419ca5e2993791;
   SUCCESS
   ```
Precautions

Explanation of incremental data push

1. The CDC incremental push is currently transactional, and the transactions of the physical database will not be split. Therefore, if there are data changes in multiple tables in a transaction, these data changes will be pushed together. If you want to support XA transactions (currently only supports openGauss), both openGauss and Proxy need the GLT module.

2. The conditions for push are met when a certain amount of data is met or a certain time interval is reached (currently 300ms). When processing XA transactions, if the received multiple physical database incremental events exceed 300ms, it may cause the XA transaction to be split and pushed.

Handling of large transactions

Currently, large transactions are fully parsed, which may cause the CDC Server process to OOM. In the future, forced truncation may be considered.

Recommended configuration

There is no fixed value for the performance of CDC, you can focus on the batchSize of read/write in the configuration, and the size of the memory queue, and tune it according to the actual situation.

9.3 Common Configuration

This chapter mainly introduces general configuration, including property configuration and built-in algorithm configuration.

9.3.1 Properties Configuration

Background

Apache ShardingSphere provides the way of property configuration to configure system level configuration.
### Parameters

<table>
<thead>
<tr>
<th>Name*</th>
<th>DataType*</th>
<th>Description</th>
<th>DefaultValue*</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql-show (?)</td>
<td>boolean</td>
<td>Whether show SQL or not in log. Print SQL details can help developers debug easier. The log details include: logic SQL, actual SQL and SQL parse result. Enable this property will log into log topic ShardingSphere-SQL, log level is INFO</td>
<td>false</td>
</tr>
<tr>
<td>sql-simple (?)</td>
<td>boolean</td>
<td>Whether show SQL details in simple style</td>
<td>false</td>
</tr>
<tr>
<td>kernel-executor-size (?)</td>
<td>int</td>
<td>The max thread size of worker group to execute SQL. One ShardingSphereDataSource will use a independent thread pool, it does not share thread pool even different data source in same JVM</td>
<td>infinite</td>
</tr>
<tr>
<td>max-connections-size-per-query (?)</td>
<td>int</td>
<td>Max opened connection size for each query</td>
<td>1</td>
</tr>
<tr>
<td>check-table-metadata-enabled (?)</td>
<td>boolean</td>
<td>Whether validate table meta data consistency when application startup or updated</td>
<td>false</td>
</tr>
</tbody>
</table>
Procedure

1. Properties configuration is directly configured in the profile used by ShardingSphere-JDBC. The format is as follows:

```
props:
  sql-show: true
```

Sample

The example of ShardingSphere warehouse contains property configurations of various scenarios. Please refer to: https://github.com/apache/shardingsphere/tree/master/examples

9.3.2 Builtin Algorithm

Introduction

Apache ShardingSphere allows developers to implement algorithms via SPI; At the same time, Apache ShardingSphere also provides a couple of builtin algorithms for simplify developers.

Usage

The builtin algorithms are configured by type and props. Type is defined by the algorithm in SPI, and props is used to deliver the customized parameters of the algorithm.

No matter which configuration type is used, the configured algorithm is named and passed to the corresponding rule configuration. This chapter distinguishes and lists all the builtin algorithms of Apache ShardingSphere according to its functions for developers’ reference.

Metadata Repository

Background

Apache ShardingSphere provides different metadata persistence methods for different running modes. Users can freely choose the most appropriate way to store metadata while configuring the running mode.
Parameters

Database Repository

Type: JDBC
Mode: Standalone
Attributes:

<table>
<thead>
<tr>
<th>Name*</th>
<th>Type*</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>provider</td>
<td>String</td>
<td>Type for metadata persist, the optional value is H2, MySQL</td>
<td>H2</td>
</tr>
<tr>
<td>jdbc_url</td>
<td>String</td>
<td>JDBC URL</td>
<td>jdbc:h2:mem:config;DB_CLOSE_DELAY=-1;DB_CLOSE_DELAY=-1;DB_CLOSE_DELAY=-1;DATBASE_TO_UPPER=false;MODE=MYSQL</td>
</tr>
<tr>
<td>username</td>
<td>String</td>
<td>username</td>
<td>sa</td>
</tr>
<tr>
<td>password</td>
<td>String</td>
<td>password</td>
<td></td>
</tr>
</tbody>
</table>

ZooKeeper Repository

Type: ZooKeeper
Mode: Cluster
Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>retryIntervalMilliseconds</td>
<td>int</td>
<td>Milliseconds of retry interval</td>
<td>500</td>
</tr>
<tr>
<td>maxRetries</td>
<td>int</td>
<td>Max retries of client connection</td>
<td>3</td>
</tr>
<tr>
<td>timeToLiveSeconds</td>
<td>int</td>
<td>Seconds of ephemeral data live</td>
<td>60</td>
</tr>
<tr>
<td>operationTimeOutMilliseconds</td>
<td>int</td>
<td>Milliseconds of operation timeout</td>
<td>500</td>
</tr>
<tr>
<td>digest</td>
<td>String</td>
<td>Password of login</td>
<td></td>
</tr>
</tbody>
</table>

Etcd Repository

Type: Etcd
Mode: Cluster
Attributes:
### Consul Repository

Due to the limitation of the Maven module of com.ecwid.consul:consul-api:1.4.5, users cannot connect to the Consul Agent through the gRPC port.

The `serverLists` property of the Consul implementation is by design and can only be connected to a single Consul Agent via an HTTP endpoint. `serverLists` uses relaxed URL matching principles. 1. When `serverLists` is empty, it will be resolved to the Consul Agent instance of http://127.0.0.1:8500. 2. When `serverLists` is `hostName`, it will be resolved to the Consul Agent instance of http://hostName:8500. 3. When `serverLists` is `hostName:port`, it will be resolved to the Consul Agent instance of http://hostName:port. 4. When `serverLists` is `http://hostName:port`, it will be resolved to the Consul Agent instance of http://hostName:port. 5. When `serverLists` is `https://hostName:port`, it will be resolved to the Consul Agent instance of https://hostName:port.

Type: Consul

Mode: Cluster

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeToLiveSeconds</td>
<td>String</td>
<td>Seconds of ephemeral instance live</td>
<td>30s</td>
</tr>
<tr>
<td>blockQueryTimeToSeconds</td>
<td>long</td>
<td>Seconds of query timeout</td>
<td>60</td>
</tr>
</tbody>
</table>

### Procedure

1. Configure running mode in server.yaml.

2. Configure metadata persistence warehouse type.

### Sample

- Standalone mode configuration method.

```yaml
mode:
  type: Standalone
repository:
  type: JDBC
  props:
    provider: H2
    jdbc_url: jdbc:h2:mem:config;DB_CLOSE_DELAY=-1;DATABASE_TO_UPPER=false;
```

9.3. Common Configuration
MODE=MYSQL
  username: test
  password: Test@123

• Cluster mode.

mode:
  type: Cluster
  repository:
    type: zookeeper
  props:
    namespace: governance_ds
    server-lists: localhost:2181
    retryIntervalMilliseconds: 500
    timeToLiveSeconds: 60
    maxRetries: 3
    operationTimeoutMilliseconds: 500

Sharding Algorithm

Background

ShardingSphere built-in algorithms provide a variety of sharding algorithms, which can be divided into automatic sharding algorithms, standard sharding algorithms, composite sharding algorithms, and hint sharding algorithms, and can meet the needs of most business scenarios of users.

Additionally, considering the complexity of business scenarios, the built-in algorithm also provides a way to customize the sharding algorithm. Users can complete complex sharding logic by writing java code.

It should be noted that the sharding logic of the automatic sharding algorithm is automatically managed by ShardingSphere and needs to be used by configuring the autoTables sharding rules.

Parameters

Auto Sharding Algorithm

Modulo Sharding Algorithm

Type: MOD
Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sharding-count</td>
<td>int</td>
<td>Sharding count</td>
</tr>
</tbody>
</table>
Hash Modulo Sharding Algorithm

Type: HASH_MOD

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sharding-count</td>
<td>int</td>
<td>Sharding count</td>
</tr>
</tbody>
</table>

Volume Based Range Sharding Algorithm

Type: VOLUME_RANGE

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>range-lower</td>
<td>long</td>
<td>Range lower bound, throw exception if lower than bound</td>
</tr>
<tr>
<td>range-upper</td>
<td>long</td>
<td>Range upper bound, throw exception if upper than bound</td>
</tr>
<tr>
<td>sharding-volume</td>
<td>long</td>
<td>Sharding volume</td>
</tr>
</tbody>
</table>

Boundary Based Range Sharding Algorithm

Type: BOUNDARY_RANGE

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sharding-ranges</td>
<td>String</td>
<td>Range of sharding border, multiple boundaries separated by commas</td>
</tr>
</tbody>
</table>

Auto Interval Sharding Algorithm

Type: AUTO_INTERVAL

Attributes:
### Standard Sharding Algorithm

Apache ShardingSphere built-in standard sharding algorithm are:

#### Inline Sharding Algorithm

With Groovy expressions that uses the default implementation of the `InlineExpressionParser` SPI, `InlineShardingStrategy` provides single-key support for the sharding operation of `=` and `IN` in SQL. Simple sharding algorithms can be used through a simple configuration to avoid laborious Java code developments. For example, `t_user_$->{u_id % 8}` means table `t_user` is divided into 8 tables according to `u_id`, with table names from `t_user_0` to `t_user_7`. Please refer to Inline Expression for more details.

Type: INLINE

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType*</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>algorithm-expression</td>
<td>String</td>
<td>Inline expression sharding algorithm</td>
</tr>
<tr>
<td>allow-range-query-with-inline-sharding (?)</td>
<td>boolean</td>
<td>Whether range query is allowed. Note: range query will ignore sharding strategy and conduct full routing</td>
</tr>
</tbody>
</table>
Interval Sharding Algorithm

This algorithm actively ignores the time zone information of datetime-pattern. This means that when datetime-lower, datetime-upper and the incoming shard key contain time zone information, time zone conversion will not occur due to time zone inconsistencies. When the incoming sharding key is java.time.Instant, there is a special case, which will carry the time zone information of the system and convert it into the string format of datetime-pattern, and then proceed to the next sharding.

Type: INTERVAL

Attributes:
<table>
<thead>
<tr>
<th>Name</th>
<th>DataType*</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>datetime-pattern</td>
<td>String</td>
<td>Timestamp pattern of sharding value, must can be transformed to Java LocalDateTime. For example: yyyy-MM-dd HH:mm:ss, yyyy-MM-dd or HH:mm:ss etc. But Gy-MM etc. related to java.time.chrono. JapaneseDate are not supported</td>
</tr>
<tr>
<td>dateti me-lower</td>
<td>String</td>
<td>Datetime sharding lower boundary, pattern is defined datetime-pattern</td>
</tr>
<tr>
<td>dateti me-upper (?)</td>
<td>String</td>
<td>Datetime sharding upper boundary, pattern is defined datetime-pattern</td>
</tr>
<tr>
<td>sha rdin g-suffix -pat tern</td>
<td>String</td>
<td>Suffix pattern of sharding data sources or tables, must can be transformed to Java LocalDateTime, must be consistent with date-time-interval-unit. For example: yyyyMM</td>
</tr>
<tr>
<td>dateti me-interval-am oun t (?)</td>
<td>int</td>
<td>Interval of sharding value, after which the next shard will be entered</td>
</tr>
<tr>
<td>da teti me-nter val-unit (?)</td>
<td>String</td>
<td>Unit of sharding value interval, must can be transformed to Java ChronoUnit’s Enum value. For example: MONTHS</td>
</tr>
</tbody>
</table>
Complex Sharding Algorithm

Complex Inline Sharding Algorithm

Please refer to Inline Expression for more details.

Type: COMPLEX_INLINE

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>sharding-columns (?)</td>
<td>String</td>
<td>sharing column names</td>
<td>.</td>
</tr>
<tr>
<td>algorithm-expression</td>
<td>String</td>
<td>Inline expression sharding algorithm</td>
<td></td>
</tr>
<tr>
<td>allow-range-query-with-inline-sharding (?)</td>
<td>boolean</td>
<td>Whether range query is allowed. Note: range query will ignore sharding strategy and conduct full routing</td>
<td>false</td>
</tr>
</tbody>
</table>

Hint Sharding Algorithm

Hint Inline Sharding Algorithm

Please refer to Inline Expression for more details.

Type: COMPLEX_INLINE

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>algorithm-expression</td>
<td>String</td>
<td>Inline expression sharding algorithm</td>
<td>${value}</td>
</tr>
</tbody>
</table>

Class Based Sharding Algorithm

Realize custom extension by configuring the sharding strategy type and algorithm class name. CLASS_BASED allows additional custom properties to be passed into the algorithm class. The passed properties can be retrieved through the java.util.Properties class instance with the property name props. Refer to Git’s org.apache.shardingsphere.example.extension.sharding.algortihm.classbased.fixture.ClassBasedStandardShardingAlgorithmFixture.

Type: CLASS_BASED

Attributes:
Name | Data Type | Description
--- | --- | ---
strategy | String | Sharding strategy type, support STANDARD, COMPLEX or HINT (case insensitive)
algorithmName | String | Fully qualified name of sharding algorithm

Procedure

1. When using data sharding, configure the corresponding data sharding algorithm under the `shardingAlgorithms` attribute.

Sample

```rules:
- !SHARDING
tables:
  t_order:
    actualDataNodes: ds_${0..1}.t_order_${0..1}
tableStrategy:
  standard:
    shardingColumn: order_id
    shardingAlgorithmName: t_order_inline
    keyGenerateStrategy:
      column: order_id
      keyGeneratorName: snowflake
t_order_item:
    actualDataNodes: ds_${0..1}.t_order_item_${0..1}
tableStrategy:
  standard:
    shardingColumn: order_id
    shardingAlgorithmName: t_order_item_inline
    keyGenerateStrategy:
      column: order_item_id
      keyGeneratorName: snowflake
t_account:
    actualDataNodes: ds_${0..1}.t_account_${0..1}
tableStrategy:
  standard:
    shardingAlgorithmName: t_account_inline
    keyGenerateStrategy:
      column: account_id
      keyGeneratorName: snowflake
defaultShardingColumn: account_id
bindingTables:
```
- t_order, t_order_item
  
  defaultDatabaseStrategy:
  
  standard:
    shardingColumn: user_id
    shardingAlgorithmName: database_inline
  
  defaultTableStrategy:
    none:

  shardingAlgorithms:
  
  database_inline:
    type: INLINE
    props:
      algorithm-expression: ds_${user_id % 2}
  
  t_order_inline:
    type: INLINE
    props:
      algorithm-expression: t_order_${order_id % 2}
  
  t_order_item_inline:
    type: INLINE
    props:
      algorithm-expression: t_order_item_${order_id % 2}
  
  t_account_inline:
    type: INLINE
    props:
      algorithm-expression: t_account_${account_id % 2}

  keyGenerators:
    snowflake:
      type: SNOWFLAKE

- [BROADCAST]

  tables:
  
  - t_address

- Core Feature: Data Sharding
- Developer Guide: Data Sharding
Key Generate Algorithm

Background

In traditional database software development, automatic primary key generation is a basic requirement and various databases provide support for this requirement, such as MySQL’s self-incrementing keys, Oracle’s self-incrementing sequences, etc.

After data sharding, it is a very tricky problem to generate global unique primary keys from different data nodes. Self-incrementing keys between different actual tables within the same logical table generate duplicate primary keys because they are not mutually perceived.

Although collisions can be avoided by constraining the initial value and step size of self-incrementing primary keys, additional O&M rules must to be introduced, making the solution lack completeness and scalability.

There are many third-party solutions that can perfectly solve this problem, such as UUID, which relies on specific algorithms to generate non-duplicate keys, or by introducing primary key generation services.

In order to cater to the requirements of different users in different scenarios, Apache ShardingSphere not only provides built-in distributed primary key generators, such as UUID, SNOWFLAKE, but also abstracts the interface of distributed primary key generators to facilitate users to implement their own customized primary key generators.

Parameters

Snowflake

Type: SNOWFLAKE

Attributes:
<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>worker-id (?)</td>
<td>long</td>
<td>The unique ID for working machine</td>
<td>0</td>
</tr>
<tr>
<td>max-tolerate-time-diff-millisconds (?)</td>
<td>long</td>
<td>The max tolerate time for different server’s time difference in milliseconds</td>
<td>10 milliseconds</td>
</tr>
<tr>
<td>max-vibration-offset (?)</td>
<td>int</td>
<td>The max upper limit value of vibrate number, range [0, 4096). Notice: To use the generated value of this algorithm as sharding value, it is recommended to configure this property. The algorithm generates key mod $2^n$ ($2^n$ is usually the sharding amount of tables or databases) in different milliseconds and the result is always 0 or 1. To prevent the above sharding problem, it is recommended to configure this property, its value is $(2^n) - 1$</td>
<td>1</td>
</tr>
</tbody>
</table>

**Note:** worker-id is optional. 1. In standalone mode, support user-defined configuration, if the user does not configure the default value of 0. 2. In cluster mode, it will be automatically generated by the system, and duplicate values will not be generated in the same namespace.
UUID

Type: UUID
Attributes: None

Procedure

1. Policy of distributed primary key configurations is for columns when configuring data sharding rules.

Sample

- Snowflake Algorithms

```yaml
keyGenerators:
snowflake:
type: SNOWFLAKE
```

- UUID

```yaml
keyGenerators:
uuid:
type: UUID
```

Load Balance Algorithm

Background

ShardingSphere built-in provides a variety of load balancer algorithms, including polling algorithm, random access algorithm and weight access algorithm, which can meet users’ needs in most business scenarios.

Moreover, considering the complexity of the business scenario, the built-in algorithm also provides an extension mode. Users can implement the load balancer algorithm they need based on SPI interface.

Parameters

Round-robin Load Balance Algorithm

Type: ROUND_ROBIN
**Random Load Balance Algorithm**

Type: RANDOM

**Weight Load Balance Algorithm**

Type: WEIGHT

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>${replica-name}</code></td>
<td>double</td>
<td>Attribute name uses the name of the replica, and the parameter fills in the weight value corresponding to the replica. Weight parameter range min &gt; 0, total &lt;= Double.MAX_VALUE.</td>
</tr>
</tbody>
</table>

**Procedure**

1. Configure a load balancer algorithm for the loadBalancers attribute to use read/write splitting.

**Sample**

```plaintext
rules:
- !READWRITE_SPLITTING
dataSources:
  readwrite_ds:
    writeDataSourceName: write_ds
    readDataSourceNames:
      - read_ds_0
      - read_ds_1
    transactionalReadQueryStrategy: PRIMARY
    loadBalancerName: random
loadBalancers:
  random:
    type: RANDOM
```

Encryption Algorithm

Background

Encryption algorithms are by the encryption features of Apache ShardingSphere. A variety of algorithms are built-in to make it easy for users to fully leverage the feature.

Parameters

Standard Encrypt Algorithm

AES Encrypt Algorithm

Type: AES
Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aes-key-value</td>
<td>String</td>
<td>AES KEY</td>
</tr>
<tr>
<td>digest-algorithm-name</td>
<td>String</td>
<td>AES KEY DIGEST ALGORITHM (optional, default: SHA-1)</td>
</tr>
</tbody>
</table>

Assisted Encrypt Algorithm

MD5 Assisted Encrypt Algorithm

Type: MD5
Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt</td>
<td>String</td>
<td>Salt value(optional)</td>
</tr>
</tbody>
</table>
Operating Procedure

1. Configure encryptors in an encryption rule.
2. Use relevant algorithm types in encryptors.

Configuration Examples

rules:
- !ENCRYPT
tables:
  t_user:
    columns:
      username:
        cipher:
          name: username
          encryptorName: name_encryptor
        likeQuery:
          name: name_like
          encryptorName: like_encryptor
encryptors:
  like_encryptor:
    type: CHAR_DIGEST_LIKE
  name_encryptor:
    type: AES
    props:
      aes-key-value: 123456abc

Shadow Algorithm

Background

The shadow DB feature carries out shadow measurement to SQL statements executed. Shadow measurement supports two types of algorithms, and users can choose one or a combination of them based on actual business needs.
Parameters

Column-based shadow algorithm

Column value matching shadow algorithm

Type: VALUE_MATCH

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>String</td>
<td>shadow column</td>
</tr>
<tr>
<td>operation</td>
<td>String</td>
<td>SQL operation type (INSERT, UPDATE, DELETE, SELECT)</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>value matched by shadow column</td>
</tr>
</tbody>
</table>

Column-based Regex matching algorithm

Type: REGEX_MATCH

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>String</td>
<td>match a column</td>
</tr>
<tr>
<td>operation</td>
<td>String</td>
<td>SQL operation type (INSERT, UPDATE, DELETE, SELECT)</td>
</tr>
<tr>
<td>regex</td>
<td>String</td>
<td>shadow column matching Regex</td>
</tr>
</tbody>
</table>

Hint-based shadow algorithm

SQL HINT shadow algorithm

Type: SQL_HINT

/* SHARDINGSHIRE_HINT: SHADOW=true */

Configuration sample

- Java API

```java
public final class ShadowConfiguration {
    // ...

    private AlgorithmConfiguration createShadowAlgorithmConfiguration() {
        Properties userIdInsertProps = new Properties();
        userIdInsertProps.setProperty("operation", "insert");
        userIdInsertProps.setProperty("column", "user_id");
        userIdInsertProps.setProperty("value", "1");
        return new AlgorithmConfiguration("VALUE_MATCH", userIdInsertProps);
    }
}
```

9.3. Common Configuration
• YAML:

```yaml
shadowAlgorithms:
  user-id-insert-algorithm:
    type: VALUE_MATCH
    props:
      column: user_id
      operation: insert
      value: 1
```

### SQL Translator

#### Native SQL translator

Type: NATIVE

Attributes: None

**Default SQL translator, does not implement yet.**

#### JooQ SQL translator

Type: JOOQ

Attributes: None

**Because of it need JooQ dependency, ShardingSphere does not include the module, please use below XML to import it by Maven.**

```xml
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-sql-translator-jooq-provider</artifactId>
  <version>${project.version}</version>
</dependency>
```
Sharding Audit Algorithm

Background

The sharding audit is to audit the SQL statements in the sharding database. Sharding audit not only intercept illegal SQL statements, but also gather the SQL statistics.

Parameters

DML_SHARDING_CONDITIONS algorithm

Type: DML_SHARDING_CONDITIONS

Procedure

1. when configuring data sharding rules, create sharding audit configurations.

Sample

- DML_SHARDING_CONDITIONS

Data Masking Algorithm

Background

Data masking algorithms are by the mask features of Apache ShardingSphere. A variety of algorithms are built-in to make it easy for users to fully leverage the feature.

Parameters

Hash Data Masking Algorithm

MD5 Data Masking Algorithm

Type: MD5

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt</td>
<td>String</td>
<td>Salt value (optional)</td>
</tr>
</tbody>
</table>
Mask Data Masking Algorithm

**Keep First N Last M Data Masking Algorithm**

Type: KEEP_FIRST_N_LAST_M

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>first-n</td>
<td>int</td>
<td>first n substring</td>
</tr>
<tr>
<td>last-m</td>
<td>int</td>
<td>last m substring</td>
</tr>
<tr>
<td>replace-char</td>
<td>String</td>
<td>replace char</td>
</tr>
</tbody>
</table>

**Keep From X To Y Data Masking Algorithm**

Type: KEEP_FROM_X_TO_Y

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>from-x</td>
<td>int</td>
<td>start position (from 0)</td>
</tr>
<tr>
<td>to-y</td>
<td>int</td>
<td>end position (from 0)</td>
</tr>
<tr>
<td>replace-char</td>
<td>String</td>
<td>replace char</td>
</tr>
</tbody>
</table>

**Mask First N Last M Data Masking Algorithm**

Type: MASK_FIRST_N_LAST_M

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>first-n</td>
<td>int</td>
<td>first n substring</td>
</tr>
<tr>
<td>last-m</td>
<td>int</td>
<td>last m substring</td>
</tr>
<tr>
<td>replace-char</td>
<td>String</td>
<td>replace char</td>
</tr>
</tbody>
</table>

**Mask From X To Y Data Masking Algorithm**

Type: MASK_FROM_X_TO_Y

Attributes:
<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>from-x</td>
<td>int</td>
<td>start position (from 0)</td>
</tr>
<tr>
<td>to-y</td>
<td>int</td>
<td>end position (from 0)</td>
</tr>
<tr>
<td>replace-char</td>
<td>String</td>
<td>replace char</td>
</tr>
</tbody>
</table>

**Mask Before Special Chars Data Masking Algorithm**

Type: MASK_BEFORE_SPECIAL_CHARS

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>special-chars</td>
<td>String</td>
<td>Special chars (first appearance)</td>
</tr>
<tr>
<td>replace-char</td>
<td>String</td>
<td>replace char</td>
</tr>
</tbody>
</table>

**Mask After Special Chars Data Masking Algorithm**

Type: MASK_AFTER_SPECIAL_CHARS

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>special-chars</td>
<td>String</td>
<td>Special chars (first appearance)</td>
</tr>
<tr>
<td>replace-char</td>
<td>String</td>
<td>replace char</td>
</tr>
</tbody>
</table>

**Replace Data Masking Algorithm**

**Generic table random replace algorithm.**

Type: GENERIC_TABLE_RANDOM_REPLACE

Attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>DataTypes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lower-case-letter-codes</td>
<td>String</td>
<td>Lowercase-letter codes (separate with comma, default value: a,b,c,d,e,f,g,h,i,j,k,l,m,n,o,p,q,r,s,t,u,v,w,x,y,z)</td>
</tr>
<tr>
<td>digital-random-codes</td>
<td>String</td>
<td>Numbers (separate with comma, default value: 0,1,2,3,4,5,6,7,8,9)</td>
</tr>
<tr>
<td>special-codes</td>
<td>String</td>
<td>Special codes (separate with comma, default value: ~,!,@,#,$,%'^',&amp;*,';:&lt;,&gt;...]</td>
</tr>
</tbody>
</table>
Operating Procedure

2. Use relevant algorithm types in maskAlgorithms.

Configuration Examples

```yaml
rules:
- !MASK
tables:
  t_user:
    columns:
    password:
      maskAlgorithm: md5_mask
    email:
      maskAlgorithm: mask_before_special_chars_mask
    telephone:
      maskAlgorithm: keep_first_n_last_m_mask

maskAlgorithms:
  md5_mask:
    type: MD5
  mask_before_special_chars_mask:
    type: MASK_BEFORE_SPECIAL_CHARS
    props:
      special-chars: '@'
      replace-char: '*'
  keep_first_n_last_m_mask:
    type: KEEP_FIRST_N_LAST_M
    props:
      first-n: 3
      last-m: 4
      replace-char: '*'
```

Row Value Expressions

Row Value Expressions that uses the Groovy syntax

Type: GROOVY

Just use `${ expression }` or `->{ expression }` in the configuration to identify the row expressions. The content of row expressions uses Groovy syntax, and all operations supported by Groovy are supported by row expressions. `${begin..end}` denotes the range interval, ${[[unit1, unit2, unit_x]]} denotes the enumeration value. If there are multiple `${ expression }` or `->{ expression }` expressions in a row expression, the final result of the whole expression will be a Cartesian combination based on the result of each sub-expression.

Example:

- `<GROOVY>t_order_${1..3}` will be converted to t_order_1, t_order_2, t_order_3
- `<GROOVY>${['online', 'offline']}_table${1..3}` will be converted to online_table1, online_table2, online_table3, offline_table1, offline_table2, offline_table3

Row Value Expressions that uses a standard list

The LITERAL implementation will not convert any symbols to the expression part, and will directly obtain the output of the standard list from the input of the standard list. This helps address the issue that Groovy expressions are inconvenient to use under GraalVM Native Image.

Type: LITERAL

Example:

- `<LITERAL>t_order_1, t_order_2, t_order_3` will be converted to t_order_1, t_order_2, t_order_3
- `<LITERAL>t_order_${1..3}` will be converted to t_order_${1..3}`
Row Value Expressions based on fixed interval that uses the Key-Value syntax

The INTERVAL implementation introduces a Key-Value style property syntax to define a set of time ranges of strings via a single line string. This is often used to simplify the definition of actual DataNodes for Sharding feature.

INTERVAL implements the method of defining multiple attributes as Key1=Value1;Key2=Value2, using ; to separate key-value pairs, and = to separate Key values and Value values.

This implementation actively ignores the time zone information of SP, which means that when DL and DU contain time zone information, no time zone conversion will occur due to inconsistent time zones.

This implementation is not sensitive to the order of key-value pairs, and the line expression does not carry the ; sign at the end.

The INTERVAL implementation introduces the following Key values:

1. P stands for the abbreviation of prefix, which means the prefix of the result list unit, usually representing the prefix format of the real table.
2. SP stands for the abbreviation of suffix pattern, which means the timestamp format of the suffix of the result list unit. It usually represents the suffix format of the real table and must follow the format of Java DateTimeFormatter. For example: yyyyMMdd, yyyyM or yyyy etc.
3. DIA stands for the abbreviation of datetime interval amount, which means the time interval of the result list unit.
4. DIU stands for the abbreviation of datetime interval unit, which means the shard key time interval unit. It must follow the enumeration value of Java java.time.temporal.ChronoUnit#toString(). For example: Months.
5. DL stands for the abbreviation of datetime lower, which means the lower bound of time. The format is consistent with the timestamp format defined by SP.
6. DU stands for the abbreviation of datetime upper, which means the upper bound value of time. The format is consistent with the timestamp format defined by SP.
7. C stands for the abbreviation of chronology, which means calendar system and must follow the format of Java java.time.chrono.Chronology#getId(). For example: Japanese, Min-guo, ThaiBuddhist. There is a default value of ISO.

Whether the Value corresponding to the Key of C is available depends on the system environment in which the JVM is located. This means that if the user needs to set C=Japanese, they may need to call java.util.Locale.setDefault(java.util.Locale.JAPAN); in the application’s startup class to modify the system environment. Discuss two JVM environments.

1. Hotspot JVM determines the return value of java.util.Locale.getDefault() at RunTime.
2. GraalVM Native Image determines the return value of java.util.Locale.getDefault() at BuildTime, which is inconsistent with the performance of Hotspot JVM. Refer to https://github.com/oracle/graal/issues/8022.

Type: INTERVAL

Example:
Row Value Expressions that use the Groovy syntax based on GraalVM Truffle’s Espresso implementation

This is an optional implementation, and you need to actively declare the following dependencies in the pom.xml of your own project. And make sure your own project is compiled with GraalVM CE 23.0.1 For JDK 17.0.9.

```
<dependencies>
  <dependency>
    <groupId>org.apache.shardingsphere</groupId>
    <artifactId>shardingsphere-infra-expr-espresso</artifactId>
    <version>${shardingsphere.version}</version>
  </dependency>
</dependencies>
```

The user must install the Espresso component via GraalVM Updater, i.e. execute the following command in bash
gu install espresso

ESPRESSO is still an experimental module that allows the use of Row Value Expressions with Groovy syntax under GraalVM Native Image through the Espresso implementation of GraalVM Truffle.

The syntax part is the same as the GROOVY implementation rules.

Type: ESPRESSO

Example:

- `<ESPRESSO>t_order_${1..3}` will be converted to `t_order_1`, `t_order_2`, `t_order_3`
- `<ESPRESSO>${['online', 'offline']}_table${1..3}` will be converted to `online_table1`, `online_table2`, `online_table3`, `offline_table1`, `offline_table2`, `offline_table3`

Procedure

When using attributes that require the use of Row Value Expressions, such as in the data sharding feature, it is sufficient to indicate the Type Name of the specific SPI implementation under the `actualDataNodes` attribute.

If the Row Value Expressions does not indicate the Type Name of the SPI, the SPI implementation of GROOVY will be used by default.

Sample

```yaml
rules:
- !SHARDING
tables:
t_order:
    actualDataNodes: <LITERAL>ds_0.t_order_0, ds_0.t_order_1, ds_1.t_order_0, ds_1.t_order_1
    tableStrategy:
      standard:
        shardingColumn: order_id
        shardingAlgorithmName: t_order_inline
    keyGenerateStrategy:
      column: order_id
      keyGeneratorName: snowflake
defaultDatabaseStrategy:
      standard:
        shardingColumn: user_id
        shardingAlgorithmName: database_inline
    shardingAlgorithms:
      database_inline:
        type: INLINE
        props:
```

- Data Sharding

9.3.3 SQL Hint

Background

At present, most relational databases basically provide SQL Hint as a supplement to SQL syntax. SQL Hint allows users to intervene in the execution process of SQL through the built-in Hint syntax of the database, to complete some special functions or realize optimization of SQL execution. ShardingSphere also provides SQL Hint syntax, allowing users to perform force route for sharding and read-write splitting, and data source pass through.

Use specification

The SQL Hint syntax of ShardingSphere needs to be written in SQL in the form of comments. The SQL Hint syntax format only supports /* */ temporarily, and the Hint content needs to start with SHARDINGSPHERE_HINT:, and then define the attribute key/value pairs corresponding to different features, separated by commas when there are multiple attributes. The SQL Hint syntax format of ShardingSphere is as follows:

```sql
/* SHARDINGSPHERE_HINT: {key} = {value}, {key} = {value} */ SELECT * FROM t_order;
```

If you use the MySQL client to connect, you need to add the -c option to retain comments, and the client defaults to --skip-comments to filter comments.
Parameters

The following attributes can be defined in ShardingSphere SQL Hint. In order to be compatible with the lower version SQL Hint syntax, the attributes defined in the alias can also be used:

<table>
<thead>
<tr>
<th>Name</th>
<th>Alias</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHARDING_DATABASE_VALUE (?)</td>
<td>shardingDatabaseValue</td>
<td>Database sharding value, used when config Hint sharding strategy</td>
<td></td>
</tr>
<tr>
<td>SHARDING_TABLE_VALUE (?)</td>
<td>shardingTableValue</td>
<td>Table sharding value, used when config Hint sharding strategy</td>
<td></td>
</tr>
<tr>
<td>WRITE_ROUTE_ONLY (?)</td>
<td>writeRouteOnly</td>
<td>Route to the write datasource when use readwrite-splitting</td>
<td>false</td>
</tr>
<tr>
<td>DATA_SOURCE_NAME (?)</td>
<td>dataSourceName</td>
<td>Data source pass through, route SQL directly to the specified data source</td>
<td></td>
</tr>
<tr>
<td>SKIP_SQL_REWRITE (?)</td>
<td>skipSQLRewrite</td>
<td>Skip the SQL rewrite phase</td>
<td>false</td>
</tr>
<tr>
<td>DISABLE_AUDIT_NAMES (?)</td>
<td>disableAuditNames</td>
<td>Disable the specified SQL audit algorithm</td>
<td></td>
</tr>
<tr>
<td>SHADOW (?)</td>
<td>shadow</td>
<td>Route to the shadow datasource when use shadow</td>
<td>false</td>
</tr>
</tbody>
</table>

SQL Hint

Sharding

The optional attributes of sharding SQL Hint include:

- `{table}.SHARDING_DATABASE_VALUE`: used to add data source sharding value corresponding to the `{table}` table, multiple attributes are separated by commas;
- `{table}.SHARDING_TABLE_VALUE`: used to add table sharding value corresponding to the
{table} table, multiple attributes are separated by commas.

In the case of only database sharding, when forcing routing to a certain datasource, you can use the SHARDING_DATABASE_VALUE method to set the sharding value without specifying {table}.

An example of using the SQL Hint of sharding:

```sql
/* SHARDINGSPHERE_HINT: t_order.SHARDING_DATABASE_VALUE=1, t_order.SHARDING_TABLE_VALUE=1 */ SELECT * FROM t_order;
```

**ReadwriteSplitting**

The optional attribute of read-write splitting SQL Hint is WRITE_ROUTE_ONLY, and true means that the current SQL is forced to be routed to write datasource for execution.

An example of using the SQL Hint for read-write splitting:

```sql
/* SHARDINGSPHERE_HINT: WRITE_ROUTE_ONLY=true */ SELECT * FROM t_order;
```

**DataSource Pass Through**

The optional attribute of datasource pass through SQL Hint is DATA_SOURCE_NAME, which needs to specify the name of the data source registered in the ShardingSphere logic database.

An example of using the SQL Hint of data source pass through:

```sql
/* SHARDINGSPHERE_HINT: DATA_SOURCE_NAME=ds_0 */ SELECT * FROM t_order;
```

**SKIP SQL REWRITE**

The optional attribute of skip SQL rewriting SQL Hint is SKIP_SQL_REWRITE, and true means skipping the current SQL rewriting stage.

An example of skipping SQL rewrite SQL Hint:

```sql
/* SHARDINGSPHERE_HINT: SKIP_SQL_REWRITE=true */ SELECT * FROM t_order;
```

**DISABLE SQL AUDIT**

The optional attribute of disable SQL audit is DISABLE_AUDIT_NAMES, you need to specify names of SQL audit algorithm that needs to be disabled, and multiple SQL audit algorithms need to be separated by commas.

An example of disable sql audit SQL Hint:
/* SHARDINGSPHERE_HINT: DISABLE_AUDIT_NAMES=sharding_key_required_auditor */ SELECT * FROM t_order;

**SHADOW**

The optional attribute of the shadow database pressure test SQL Hint is SHADOW, and true means that the current SQL will be routed to the shadow database data source for execution.

An example of using shadow SQL Hint:

/* SHARDINGSPHERE_HINT: SHADOW=true */ SELECT * FROM t_order;

### 9.4 Error Code

This chapter lists error codes of Apache ShardingSphere. They include SQL error codes and server error codes.

All contents of this chapter are draft, the error codes maybe need to adjust.

#### 9.4.1 SQL Error Code

SQL error codes provide by standard SQL State, Vendor Code and Reason, which return to client when SQL execute error.

The error codes are draft, still need to be adjusted.
### Kernel Exception

</tbody>
</table>
Apache ShardingSphere provides dozens of SPI based extensions. It is very convenient to customize the functions for developers.

This chapter lists all SPI extensions of Apache ShardingSphere. If there is no special requirement, users can use the built-in implementation provided by Apache ShardingSphere; advanced users can refer to the interfaces for customized implementation.

Apache ShardingSphere community welcomes developers to feed back their implementations to the open-source community, so that more users can benefit from it.

10.1 Mode

10.1.1 StandalonePersistRepository

Fully-qualified class name

`org.apache.shardingsphere.mode.repository.standalone.StandalonePersistRepository`

Apache ShardingSphere provides test engines for integration, module and performance.

### 11.1 Integration Test

Provide point to point test which connect real ShardingSphere and database instances. They define SQLs in XML files, engine run for each database independently. All test engines designed to modify the configuration files to execute all assertions without any Java code modification. It does not depend on any third-party environment, ShardingSphere-Proxy and database used for testing are provided by docker image.

### 11.2 Module Test

Provide module test engine for complex modules. They define SQLs in XML files, engine run for each database independently too. It includes SQL parser and SQL rewriter modules.

### 11.3 Performance Test

Provide multiple performance test methods, includes Sysbench, JMH or TPCC and so on.
### 11.4 Sysbench Test

### 11.5 Integration Test

#### 11.5.1 Design

The integration testing consists of three modules: test case, test environment and test engine.

**Test case**

It is used to define the SQL to be tested and the assertion data of the test results. Each case defines one SQL, which can define multiple database execution types.

**Test environment**

It is used to set up the database and ShardingSphere-Proxy environment for running test cases. The environment is classified into environment preparation mode, database type, and scenario.

Environment preparation mode is divided into Native and Docker, and Embed type will be supported in the future. - Native environment is used for test cases to run directly in the test environment provided by the developer, suitable for debugging scenarios; - Docker environment is directly built when Maven runs the Docker-Compose plug-in. It is suitable for cloud compilation environment and testing ShardingSphere-Proxy, such as GitHub Action; - Embed environment is built when the test framework automatically builds embedded MySQL. It is suitable for the local environment test of ShardingSphere-JDBC.

Currently, the Native environment is adopted by default, and ShardingSphere-JDBC + H2 database is used to run test cases. Maven’s `-pit. Env.docker` parameter specifies how the Docker environment is run. In the future, ShardingSphere-JDBC + MySQL of the Embed environment will be adopted to replace the default environment type used when Native executes test cases.

Database types currently support MySQL, PostgreSQL, SQLServer, and Oracle, and test cases can be executed using ShardingSphere-JDBC or ShardingSphere-Proxy.

Scenarios are used to test the supporting rules of ShardingSphere. Currently, data sharding and read/write splitting and other related scenarios are supported, and the combination of scenarios will be improved continuously in the future.
**Test engine**

It is used to read test cases in batches and execute and assert test results line by line.

The test engine arranges test cases and environments to test as many scenarios as possible with the fewest test cases.

Each SQL generates a test report in the combination of database type * access port type * SQL execution mode * JDBC execution mode * Scenario. Currently, each dimension is supported as follows:

- Database types: H2, MySQL, PostgreSQL, SQLServer, and Oracle;
- Access port types: ShardingSphere-JDBC and ShardingSphere-Proxy;
- SQL execution modes: Statement and PreparedStatement;
- JDBC execution modes: execute and executeQuery/executeUpdate;
- Scenarios: database shards, table shards, read/write splitting and sharding + read/write splitting

Therefore, one SQL will drive Database type (5) * Access port type (2) * SQL execution mode (2) * JDBC execution mode (2) * Scenario (4) = 160 test cases to be run to achieve the pursuit of high quality.

### 11.5.2 User Guide

Module path: test/e2e/sql

**Test case configuration**

SQL test case is in resources/cases/${SQL-TYPE}/${SQL-TYPE}-integration-test-cases.xml.

The case file format is as follows:

```xml
<integration-test-cases>
  <test-case sql="${SQL}"
    <assertion parameters="${value_1}:${type_1}, ${value_2}:${type_2}"
      expected-data-file="${dataset_file_1}.xml" />
    <!-- ... more assertions -->
    <assertion parameters="${value_3}:${type_3}, ${value_4}:${type_4}"
      expected-data-file="${dataset_file_2}.xml" />
  </test-case>
  <!-- ... more test cases -->
</integration-test-cases>
```

The lookup rule of expected-data-file is as follows: 1. Find the file dataset\ ${SCENARIO_NAME}\${DATABASE_TYPE}\${dataset_file}.xml in the same level directory; 2. Find the file dataset\ ${SCENARIO_NAME}\${dataset_file}.xml in the same level directory;
3. Find the file `dataset\${dataset_file}.xml` in the same level directory; 4. Report an error if none of them are found.

The assertion file format is as follows:

```xml
<dataset>
  <metadata>
    <column name="column_1" />
    <!-- ... more columns -->
    <column name="column_n" />
  </metadata>
  <row values="value_01, value_02" />
  <!-- ... more rows -->
  <row values="value_n1, value_n2" />
</dataset>
```

e2e operation module is E2E test, does not contains the assertion for `<dataset>` tag

**Environment configuration**

`${SCENARIO-TYPE}` Refers to the scenario name used to identify a unique scenario during the test engine run. `${DATABASE-TYPE}` refers to the database types.

**Native environment configuration**

Directory: `src/test/resources/env/${SCENARIO-TYPE}`
- `scenario-env.properties`: data source configuration;
- `rules.yaml`: rule configuration;
- `databases.xml`: name of the real database;
- `dataset.xml`: initialize the data;
- `init-sql\${DATABASE-TYPE}\init.sql`: initialize the database and table structure;
- `authority.xml`: to be supplemented.

**Docker environment configuration**

Directory: `src/test/resources/docker/${SCENARIO-TYPE}`
- `docker-compose.yml`: Docker-Compose config files, used for Docker environment startup;
- `proxy/conf/config-${SCENARIO-TYPE}.yaml`: rule configuration.

The Docker environment configuration provides a remote debugging port for ShardingSphere-Proxy. You can find the second exposed port for remote debugging in ``shardingsphere-proxy`` of the ``docker-compose. yaml`` file.

11.5. Integration Test
Run the test engine

Configure the running environment of the test engine

Control the test engine by configuring `src/test/resources/env/engine-env.properties`. All attribute values can be dynamically injected via Maven command line `-D`.

```properties
# Scenario type. Multiple values can be separated by commas. Optional values: db, tbl, dbtbl_with_replica_query, replica_query
it.scenarios=db,tbl,dbtbl_with_replica_query,replica_query

# Whether to run additional test cases
it.run.additional.cases=false

# Configure the environment type. Only one value is supported. Optional value: docker or null. The default value: null.
it.cluster.env.type=${it.env}

# Access port types to be tested. Multiple values can be separated by commas. Optional value: jdbc, proxy. The default value: jdbc
it.cluster.adapters=jdbc

# Scenario type. Multiple values can be separated by commas. Optional value: H2, MySQL, Oracle, SQLServer, PostgreSQL
it.cluster.databases=H2,MySQL,Oracle,SQLServer,PostgreSQL
```

Run debugging mode

- Standard test engine Run `org.apache.shardingsphere.test.integration.engine.${SQL-TYPE}.General${SQL-TYPE}E2EIT` to start the test engines of different SQL types.
- Batch test engine Run `org.apache.shardingsphere.test.integration.engine.dml.BatchDMLE2EIT` to start the batch test engine for the test `addBatch()` provided for DML statements.
- Additional test engine Run `org.apache.shardingsphere.test.integration.engine.${SQL-TYPE}.Additional${SQL-TYPE}E2EIT` to start the test engine with more JDBC method calls. Additional test engines need to be enabled by setting `it.run.additional.cases=true`. 
**Run Docker mode**

```bash
./mvnw -B clean install -f test/e2e/pom.xml -Pit.env.docker -Dit.cluster.adapters=proxy,jdbc -Dit.scenarios=${scenario_name_1,scenario_name_2,scenario_name_n} -Dit.cluster.databases=MySQL
```

Run the above command to build a Docker mirror `apache/shardingsphere-proxy-test:latest` used for integration testing. If you only modify the test code, you can reuse the existing test mirror without rebuilding it. Skip the mirror building and run the integration testing directly with the following command:

```bash
./mvnw -B clean install -f test/e2e/sql/pom.xml -Pit.env.docker -Dit.cluster.adapters=proxy,jdbc -Dit.scenarios=${scenario_name_1,scenario_name_2,scenario_name_n} -Dit.cluster.databases=MySQL
```

**Remote debug Proxy code in Docker container**

First of all, you need to modify the configuration file `it-env.properties`, set `function.it.env.type` to `docker`, and then set the corresponding database image version like `transaction.it.docker.mysql.version=mysql:5.7`. Then generate the test image through the command, for example:

```bash
# for operation, replace ${operation} with transaction, pipeline or showprocesslist
./mvnw -B clean install -am -pl test/e2e/operation/${operation} -Pit.env.docker -DskipTests
```

```bash
# for e2e sql
./mvnw -B clean install -am -pl test/e2e/sql -Pit.env.docker -DskipTests -Dspotless.apply.skip=true
```

**Remote debug Proxy started by docker image**

E2E Test Proxy image opens the 3308 port by default for remote debugging of the instance in the container. Use the following method to connect and debug the Proxy code in the container with IDE tools such as IDEA:

IDEA -> Run -> Edit Configurations -> Add New Configuration -> Remote JVM Debug

Edit the corresponding information:
- **Name**: A descriptive name, such as `e2e-debug`.
- **Host**: A IP that can access docker, such as `127.0.0.1`.
- **Port**: debugging port (will set in next step).
- **use module classpath**: The root directory of the project `shardingsphere`.

After editing the above information, run Run -> Run -> e2e-debug in IDEA to start the remote debug of IDEA.
**Remote debug Proxy started by Testcontainer**

Note: If the Proxy container is started by Testcontainer, because the 3308 port is not exposed before Testcontainer starts, it cannot be debugged by the Remote debug Proxy started by docker image method. Debug Testcontainer started Proxy container by the following method: - Set a breakpoint in the relevant startup class of Testcontainer, for example, after the line `containerComposer.start();` in `BaseE2EIT#setUp()` in the suite test, at this time, the relevant containers must have been started. - Access breakpoint debugging mode through shortcut key Alt + F8, and view the port mapped by the 3308 mapping of the Proxy object under the containerComposer (the external mapping port of Testcontainer is random). For example, the expression `((ShardingSphereProxyClusterContainer)((java.util.LinkedList)((ITContainers)((ClusterContainerComposer)containerComposer).containers).dockerContainers).getLast()).getMappedPort(3308)` get the mapped random port 51837. (or get mapped port by `docker ps`). See the Remote debug Proxy started by docker image method, set the Name, Host, Port, and use the port got in previous step, e.g. 51837.

After editing the above information, run Run -> Run -> e2e-debug -> debug in IDEA to start the remote debug of IDEA.

**Notice**

1. To test Oracle, add an Oracle driver dependency to pom.xml.
2. In order to ensure the integrity and legibility of the test data, 10 database shards and 10 table shards are used in the sharding of the integration testing, which takes a long time to run the test cases completely.

**11.6 Performance Test**

Provides result for each performance test tools.

**11.6.1 SysBench ShardingSphere-Proxy Empty Rule Performance Test**

**Objectives**

Compare the performance of ShardingSphere-Proxy and MySQL. 1. Sysbench directly carries out stress testing on the performance of MySQL. 1. Sysbench directly carries out stress testing on ShardingSphere-Proxy (directly connect MySQL).

Based on the above two groups of experiments, we can figure out the loss of MySQL when using ShardingSphere-Proxy.
Set up the test environment

Server information

1. Db-related configuration: it is recommended that the memory is larger than the amount of data to be tested, so that the data is stored in the memory hot block, and the rest can be adjusted.

2. ShardingSphere-Proxy-related configuration: it is recommended to use a high-performance, multi-core CPU, and other configurations can be customized.

3. Disable swap partitions on all servers involved in the stress testing.

Database

```sql
[mysqld]
innodb_buffer_pool_size=${MORE_THAN_DATA_SIZE}
nnodb-log-file-size=3000000000
innodb-log-files-in-group=5
innodb-flush-log-at-trx-commit=0
innodb-change-buffer-max-size=40
back_log=900
innodb_max_dirty_pages_pct=75
innodb_open_files=20480
innodb_buffer_pool_instances=8
innodb_page_cleaners=8
innodb_purge_threads=2
innodb_read_io_threads=8
innodb_write_io_threads=8
table_open_cache=102400
log_timestamps=system
thread_cache_size=16384
transaction_isolation=READ-COMMITTED
```

# Appropriate tuning can be considered to magnify the underlying DB performance, so that the experiment doesn't subject to DB performance bottleneck.
Stress testing tool

Refer to sysbench’s GitHub

ShardingSphere-Proxy

bin/start.sh

-Xmx16g -Xms16g -Xmn8g  # Adjust JVM parameters

cfg.yaml

databaseName: sharding_db

dataSources:
  ds_0:
    url: jdbc:mysql://***.***.***.***:****/test?serverTimezone=UTC&useSSL=false

Parameters can be adjusted appropriately
    username: test

    connectionTimeoutMilliseconds: 30000
    idleTimeoutMilliseconds: 60000
    maxLifetimeMilliseconds: 1800000
    maxPoolSize: 200  # The maximum ConnPool is set to ${the number of concurrencies in stress testing}, which is consistent with the number of concurrencies in stress testing to shield the impact of additional connections in the process of stress testing.
    minPoolSize: 200  # The minimum ConnPool is set to ${the number of concurrencies in stress testing}, which is consistent with the number of concurrencies in stress testing to shield the impact of connections initialization in the process of stress testing.

rules: []

Test phase

Environment setup

sysbench oltp_read_write --mysql-host=${DB_IP} --mysql-port=${DB_PORT} --mysql-user=${USER} --mysql-password=${PASSWD} --mysql-db=test --tables=10 --table-size=1000000 --report-interval=10 --time=100 --threads=200 cleanup

sysbench oltp_read_write --mysql-host=${DB_IP} --mysql-port=${DB_PORT} --mysql-user=${USER} --mysql-password=${PASSWD} --mysql-db=test --tables=10 --table-size=1000000 --report-interval=10 --time=100 --threads=200 prepare

11.6. Performance Test
**Stress testing command**

```bash
sysbench oltp_read_write --mysql-host=${DB/PROXY_IP} --mysql-port=${DB/PROXY_PORT} --mysql-user=${USER} --mysql-password=${PASSWD} --mysql-db=test --tables=10 --table-size=1000000 --report-interval=10 --time=100 --threads=200 run
```

**Stress testing report analysis**

sysbench 1.0.20 (using bundled LuaJIT 2.1.0-beta2)

Running the test with following options:

- Number of threads: 200
- Report intermediate results every 10 second(s)
- Initializing random number generator from current time
- Initializing worker threads...

# Report test results every 10 seconds, and the number of tps, reads per second, writes per second, and the total response time of more than 95th percentile.

<table>
<thead>
<tr>
<th>Time</th>
<th>Threads</th>

SQL statistics:

- **queries performed:**
  - read: 19560590 # number of reads
  - write: 5588740 # number of writes
  - other: 27943700 # number of other operations (COMMIT etc.)
- total: 27943700 # the total number of transactions
- transactions (per second): 1397185 (11638.59 per sec.) # number of transactions (per second)
- statements executed (per second): 27943700 (232771.76 per sec.) # number of statements executed (per second)
- ignored errors (per second): 0 (0.00 per sec.) # number of ignored errors (per second)
- reconnects (per second): 0 (0.00 per sec.) # number of reconnects (per second)

General statistics:

- total time: 120.0463s # total time
- total number of events: 1397185 # total number of transactions
### Latency (ms):

- **min:** 5.37  
  # minimum latency
- **avg:** 17.13  
  # average latency
- **max:** 109.75  
  # maximum latency
- **95th percentile:** 24.83  
  # average response time of over 95th percentile.

- **sum:** 23999546.19

### Threads fairness:

- **events (avg/stddev):** 6985.9250/34.74  
  # On average, 6985.9250 events were completed per thread, and the standard deviation is 34.74
- **execution time (avg/stddev):** 119.9977/0.01  
  # The average time of each thread is 119.9977 seconds, and the standard deviation is 0.01

### Noticeable features

1. CPU utilization ratio of the server where ShardingSphere-Proxy resides. It is better to make full use of CPU.
2. I/O of the server disk where the DB resides. The lower the physical read value is, the better.
3. Network IO of the server involved in the stress testing.

### 11.6.2 BenchmarkSQL ShardingSphere-Proxy Sharding Performance Test

#### Objective

BenchmarkSQL tool is used to test the sharding performance of ShardingSphere-Proxy.

#### Method

ShardingSphere-Proxy supports the TPC-C test through BenchmarkSQL 5.0. In addition to the content described in this document, BenchmarkSQL is operated according to the original document HOW-TO-RUN.txt.
Fine tuning to test tools

Unlike stand-alone database stress testing, distributed database solutions inevitably face trade-offs in functions. It is recommended to make the following adjustments when using BenchmarkSQL to carry out stress testing on ShardingSphere-Proxy.

Remove the foreign key and extraHistID

Modify `run/runDatabaseBuild.sh` in the BenchmarkSQL directory at line 17.

Before modification:

```
AFTER_LOAD="indexCreates foreignKeys extraHistID buildFinish"
```

After modification:

```
AFTER_LOAD="indexCreates buildFinish"
```

Stress testing environment or parameter recommendations

Note: None of the parameters mentioned in this section are absolute values and need to be adjusted based on actual test results.

It is recommended to run ShardingSphere using Java 17

ShardingSphere can be compiled using Java 8.

When using Java 17, maximize the ShardingSphere performance by default.

ShardingSphere data sharding recommendations

The data sharding of BenchmarkSQL can use the warehouse id in each table as the sharding key.

One of the tables `bmsql_item` has no warehouse id and has a fixed data volume of 100,000 rows:

- You can take `i_id` as a sharding key. However, the same Proxy connection may hold connections to multiple different data sources at the same time.
- Or you can give up sharding and store it in a single data source. But a data source may be under great pressure.
- Or you may choose range-based sharding for `i_id`, such as 1-50000 for data source 0 and 50001-100000 for data source 1.

BenchmarkSQL has the following SQL involving multiple tables:

```sql
SELECT c_discount, c_last, c_credit, w_tax
FROM bmsql_customer
JOIN bmsql_warehouse ON (w_id = c_w_id)
WHERE c_w_id = ? AND c_d_id = ? AND c_id = ?
```
If the warehouse id is used as the sharding key, the tables involved in the above SQL can be configured as bindingTable:

rules:
- !SHARDING
  bindingTables:
  - bmsql_warehouse, bmsql_customer
  - bmsql_stock, bmsql_district, bmsql_order_line

For the data sharding configuration with warehouse id as the sharding key, refer to the appendix of this document.

**PostgreSQL JDBC URL parameter recommendations**

Adjust the JDBC URL in the configuration file used by BenchmarkSQL, that is, the value of the parameter name conn: - Adding the parameter `defaultRowFetchSize=50` may reduce the number of fetch for multi-row result sets. You need to increase or decrease the number according to actual test results. - Adding the parameter `reWriteBatchedInserts=true` may reduce the time spent on bulk inserts, such as preparing data or bulk inserts for the New Order business. Whether to enable the operation depends on actual test results.

props.pg file excerpt. It is suggested to change the parameter value of conn in line 3.

```java
db=postgres
driver=org.postgresql.Driver
conn=jdbc:postgresql://localhost:5432/postgres?defaultRowFetchSize=50&
reWriteBatchedInserts=true
user=benchmarksql
password=PWbmsql
```
ShardingSphere-Proxy server.yaml parameter recommendations

The default value of `proxy-backend-query-fetch-size` is -1. Changing it to about 50 can minimize the number of fetch for multi-row result sets.

The default value of `proxy-frontend-executor-size` is CPU * 2 and can be reduced to about CPU * 0.5 based on actual test results. If NUMA is involved, set this parameter to the number of physical cores per CPU based on actual test results.

server.yaml file excerpt:

```yaml
props:
  proxy-backend-query-fetch-size: 50
# proxy-frontend-executor-size: 32 # 4*32C aarch64
# proxy-frontend-executor-size: 12 # 2*12C24T x86
```

Appendix

BenchmarkSQL data sharding reference configuration

Adjust pool size according to the actual stress testing process.

```sql
SELECT o_c_id  
FROM bmsql_oorder  
WHERE o_w_id = ? AND o_d_id = ? AND o_id = ?
```

stmtDeliveryBGUpdateOrder
11.7 Module Test

Provides test engine with each complex modules.

11.7.1 SQL Parser Test

Prepare Data

Not like Integration test, SQL parse test does not need a specific database environment, just define the sql to parse, and the assert data:

SQL Data

As mentioned sql-case-id in Integration test, test-case-id could be shared in different module to test, and the file is at shardingsphere-sql-parser/shardingsphere-sql-parser-test/src/main/resources/sql/supported/${SQL-TYPE}/*.xml
**Assert Data**

The assert data is at `shardingsphere-sql-parser/shardingsphere-sql-parser-test/src/main/resources/case/${SQL-TYPE}/*.xml` in that xml file, it could assert against the table name, token or sql condition and so on. For example:

```xml
<parser-result-sets>
  <parser-result sql-case-id="insert_with_multiple_values">
    <tables>
      <table name="t_order" />
    </tables>
    <tokens>
      <table-token start-index="12" table-name="t_order" length="7" />  
    </tokens>
    <sharding-conditions>
      <and-condition>
        <condition column-name="order_id" table-name="t_order" operator="EQUAL">
          <value literal="1" type="int" />
        </condition>
        <condition column-name="user_id" table-name="t_order" operator="EQUAL">
          <value literal="1" type="int" />
        </condition>
      </and-condition>
      <and-condition>
        <condition column-name="order_id" table-name="t_order" operator="EQUAL">
          <value literal="2" type="int" />
        </condition>
        <condition column-name="user_id" table-name="t_order" operator="EQUAL">
          <value literal="2" type="int" />
        </condition>
      </and-condition>
    </sharding-conditions>
  </parser-result>
</parser-result-sets>
```

When these configs are ready, launch the test engine in `shardingsphere-sql-parser/shardingsphere-sql-parser-test` to test SQL parse.
### 11.7.2 SQL Rewrite Test

**Target**

Facing logic databases and tables cannot be executed directly in actual databases. SQL rewrite is used to rewrite logic SQL into rightly executable ones in actual databases, including two parts, correctness rewrite and optimization rewrite. rewrite tests are for these targets.

**Test**

The rewrite tests are in the test folder under `sharding-core/sharding-core-rewrite`. Followings are the main part for rewrite tests:

- test engine
- environment configuration
- assert data

Test engine is the entrance of rewrite tests, just like other test engines, through Junit `Parameterized`, read every and each data in the xml file under the target test type in `test\resources`, and then assert by the engine one by one.

Environment configuration is the yaml file under test type under `test\resources\yaml`. The configuration file contains `dataSources`, `shardingRule`, `encryptRule` and other info. For example:

```yaml
dataSources:
  db: !!com.zaxxer.hikari.HikariDataSource
    driverClassName: org.h2.Driver
    jdbcUrl: jdbc:h2:mem:db;DB_CLOSE_DELAY=-1;DATABASE_TO_UPPER=false;MODE=MYSQL
    username: sa
    password:

## sharding Rules
rules:
- !SHARDING
  tables:
    t_account:
      actualDataNodes: db.t_account_{0..1}
    tableStrategy:
      standard:
        shardingColumn: account_id
        shardingAlgorithmName: account_table_inline
      keyGenerateStrategy:
        column: account_id
        keyGeneratorName: snowflake
    t_account_detail:
      actualDataNodes: db.t_account_detail_{0..1}
      tableStrategy:
        standard:
```

---

## 11.7. Module Test
Assert data are in the xml under test type in test\resources. In the xml file, yaml-rule means the environment configuration file path, input contains the target SQL and parameters, output contains the expected SQL and parameters. The db-type described the type for SQL parse, default is SQL92. For example:

```xml
<rewrite-assertions yml-rule="yaml/sharding/sharding-rule.yaml">
  <!-- to change SQL parse type, change db-type -->
  <rewrite-assertion id="create_index_for_mysql" db-type="MySQL">
    <input sql="CREATE INDEX index_name ON t_account ('status')" />
    <output sql="CREATE INDEX index_name ON t_account_0 ('status')" />
    <output sql="CREATE INDEX index_name ON t_account_1 ('status')" />
  </rewrite-assertion>
</rewrite-assertions>
```

After set up the assert data and environment configuration, rewrite test engine will assert the corresponding SQL without any Java code modification.

### 11.8 Pipeline E2E Test

#### 11.8.1 Objectives

Verify the functional correctness of pipeline scenarios.
11.8.2 Test environment type

Currently, NATIVE and DOCKER are available. 1. NATIVE: Run on developer local machine. Need to start ShardingSphere-Proxy instance and database instance by developer. It could be used for local debugging. 2. DOCKER: Run on docker started by Maven plugin. It could be used for GitHub Actions, and it could be used for local debugging too.

Supported databases: MySQL, PostgreSQL and openGuass.

11.8.3 User guide

Module path: test/e2e/operation/pipeline.

Environment setup

${DOCKER-IMAGE} refers to the name of a docker mirror, such as mysql:5.7. ${DATABASE-TYPE} refers to database types.

Test case

Test case example: MySQLMigrationGeneralE2EIT. Functions included: - Database-level migration (all tables). - Table-level migration (any number). - Verify migration data consistency. - Support restart during data migration. - Support integer primary keys during data migration. - Support string primary keys during data migration. - A non-administrator account can be used to migrate data.

Running the test case

Any property of it-env.properties could be defined by Maven command line parameter -D, and its priority is higher than configuration file.

NATIVE environment setup

Refer to following files for proxy server.yaml configuration: - test/e2e/operation/pipeline/src/test/resources/env/mysql/server-8.yaml -
2. Start registry center (e.g. ZooKeeper) and database.

3. Take MySQL as an example, `it-env.properties` could be configured as follows:

```properties
pipeline.it.env.type=NATIVE
pipeline.it.native.database=mysql
pipeline.it.native.mysql.username=root
pipeline.it.native.mysql.password=root
pipeline.it.native.mysql.port=3306
```

4. Find test class and start it on IDE.

**DOCKER environment setup**

Refer to `.github/workflows/e2e-pipeline.yml` for more details.

1. Build docker image.

   ```bash
   ./mvnw -B clean install -am -pl test/e2e/operation/pipeline -Pit.env.docker -DskipTests
   ```

   Running the above command will build a docker image `apache/shardingsphere-proxy-test:latest`.

   The docker image has port 3308 for remote debugging.

   If only test code is modified, you could reuse existing docker image.

2. Configure `it-env.properties`.

   ```properties
   pipeline.it.env.type=DOCKER
   pipeline.it.docker.mysql.version=mysql:5.7
   ```

3. Run test cases.

   Take MySQL as an example:

   ```bash
   ./mvnw -nsu -B install -f test/e2e/operation/pipeline/pom.xml -Dpipeline.it.env.type=docker -Dpipeline.it.docker.mysql.version=mysql:5.7
   ```
This chapter contains a section of technical implementation with Apache ShardingSphere, which provide the reference with users and developers.

### 12.1 Database Compatibility

#### SQL compatibility

SQL is the standard language for users to communicate with databases. The SQL parsing engine is responsible for parsing SQL strings into abstract syntax trees so that Apache ShardingSphere can understand and implement its incremental function. ShardingSphere currently supports MySQL, PostgreSQL, SQLServer, Oracle, openGauss, and SQL dialects conforming to the SQL92 standard. Due to the complexity of SQL syntax, a few SQL are not supported for now.
• Database protocol compatibility

Apache ShardingSphere currently implements MySQL and PostgreSQL protocols according to different data protocols.

• Supported features

Apache ShardingSphere provides distributed collaboration capabilities for databases. At the same time, it abstracts some database features to the upper layer for unified management, so as to facilitate users. Therefore, native SQL will not deliver the features provided uniformly to the database, and a message will be displayed indicating that the operation is not supported. Users can replace it with methods provided by ShardingSphere.

### 12.2 Database Gateway

Apache ShardingSphere provides the ability for SQL dialect translation to achieve automatic conversion between database dialects. For example, users can use MySQL client to connect ShardingSphere and send SQL based on MySQL dialect. ShardingSphere can automatically identify user protocol and storage node type, automatically complete SQL dialect conversion, and access heterogeneous storage nodes such as PostgreSQL.

### 12.3 Management

#### 12.3.1 Data Structure in Registry Center

Under a defined namespace, rules, props and metadata nodes persist in YAML. Modifying nodes can dynamically refresh configurations. nodes persist the runtime node of the database access object, to distinguish different database access instances. statistics persist data records in system tables.

```

/nodes/compute_nodes

It includes running instance information of database access object, with sub-nodes as the identifiers of the currently running instance, which is automatically generated at each startup using UUID.

The identifiers are temporary nodes, which are registered when instances are online and cleared when instances are offline. The registry center monitors the change of those nodes to govern the database access of running instances and other things.

/nodes/storage_nodes

It can orchestrate a replica database, and delete or disable data dynamically.

12.4 Sharding

The figure below shows how sharding works. According to whether query and optimization are needed, it can be divided into the Simple Push Down process and SQL Federation execution engine process. Simple Push Down process consists of SQL parser => SQL binder => SQL router => SQL rewriter => SQL executor => result merger, mainly used to deal with SQL execution in standard sharding scenarios. SQL Federation execution engine consists of SQL parser => SQL binder => logical optimization => physical optimization => data fetcher => operator calculation. This process performs logical optimization and physical optimization internally, during which the standard kernel procedure is adopted to route, rewrite, execute and merge the optimized logical SQL.
12.4.1 SQL Parser

It is divided into the lexical parser and syntactic parser. SQL is first split into indivisible words through a lexical parser.

The syntactic parser is then used to analyze SQL and ultimately extract the parsing context, which can include tables, options, ordering items, grouping items, aggregation functions, pagination information, query conditions, and placeholders that may be modified.
12.4.2 SQL Route

The sharding strategy configured by the user is matched according to the parsing context and the routing path is generated. Currently, sharding router and broadcast router are supported.

12.4.3 SQL Rewrite

Rewrite SQL into statements that can be executed correctly in a real database. SQL rewriting is divided into rewriting for correctness and rewriting for optimization.

12.4.4 SQL Execution

It executes asynchronously through a multithreaded executor.

12.4.5 Result Merger

It merges multiple execution result sets to achieve output through the unified JDBC interface. The result merger includes the stream merger, memory merger and appended merger using decorator mode.

12.4.6 Query Optimization

Supported by the experimental Federation Execution Engine, it optimizes complex queries such as associated queries and sub-queries and supports distributed queries across multiple database instances. It internally optimizes query plans using relational algebra to query results through optimal plans.

12.4.7 Parse Engine

SQL is relatively simple compared with other programming languages, but it’s still a complete programming language. Therefore, there’s no essential difference between parsing SQL syntax and parsing other languages (such as Java, C and Go, etc.).

Abstract Syntax Tree

The parsing process is divided into lexical parsing and syntactic parsing. The lexical parser is used to split SQL into indivisible atomic symbols called Tokens.

Tokens are classified into keywords, expressions, literals, and operators based on the dictionaries provided by different database dialects. The syntactic parser is then used to convert the output of the lexical parser into an abstract syntax tree.

For example:

```
SELECT id, name FROM t_user WHERE status = 'ACTIVE' AND age > 18
```
After the above SQL is parsed, its AST (Abstract Syntax Tree) is as follows:

The tokens for keywords in the AST are green, while the tokens for variables are red, and gray ones indicate that further splitting is required.

Finally, the domain model is traversed through the abstract syntax tree by visitor; the context required for sharding is extracted through the domain model (SQLStatement); and then, mark locations that may need rewriting.

The parsing context for sharding includes select items, table, sharding condition, auto-increment primary key, and Order By, Group By, and pagination information (Limit, Rownum, Top). The SQL parsing process is irreversible.

Each Token is parsed in the original SQL order, providing high performance. Taking the similarities and differences of SQL dialects of various databases into consideration, the SQL dialect dictionary of various databases is provided in the parsing module.

**SQL Parser Engine**

**Iteration**

SQL parsing is the core of sharding solutions, and its performance and compatibility are the most important indicators. ShardingSphere’s SQL parser has undergone three iterations and upgrades.

To achieve high performance and fast implementation, the first generation of SQL parsers used Druid prior to V1.4.x. In practical tests, its performance far exceeds that of other parsers.
The second generation of SQL parsers started from V1.5.x. ShardingSphere uses a completely self-developed SQL parsing engine. Owing to different purposes, ShardingSphere does not need to convert SQL into a complete abstract syntax tree, nor does it require a second traversal through the accessor pattern. It uses a half-parsing method to extract only the context required by data sharding, thus further improving the performance and compatibility of SQL parsing.

The third generation of SQL parsers, starting with V3.0.x, attempts to use ANTLR as a generator of SQL parsing engines and uses Visit to obtain SQL statements from the AST. Since V5.0.x, the architecture of the parsing engine has been restructured and adjusted. Moreover, the AST obtained from the first parsing is stored in the cache so that the parsing results of the same SQL can be directly obtained next time to improve parsing efficiency. Therefore, it is recommended that you use PreparedStatement, a SQL-precompiled method, to improve performance.

**Features**

- Independent SQL parsing engine
- The syntax rules can be easily expanded and modified (using ANTLR)
- Support multiple dialects

<table>
<thead>
<tr>
<th>Database</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL</td>
<td>perfect supported</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>perfect supported</td>
</tr>
<tr>
<td>SQLServer</td>
<td>supported</td>
</tr>
<tr>
<td>Oracle</td>
<td>supported</td>
</tr>
<tr>
<td>SQL92</td>
<td>supported</td>
</tr>
<tr>
<td>openGauss</td>
<td>supported</td>
</tr>
</tbody>
</table>

**API Usage**

- Introducing Maven dependency

```xml
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-sql-parser-engine</artifactId>
  <version>${project.version}</version>
</dependency>

<!-- According to the needs, introduce the parsing module of the specified dialect (take MySQL as an example), you can add all the supported dialects, or just what you need -->
<dependency>
  <groupId>org.apache.shardingsphere</groupId>
  <artifactId>shardingsphere-sql-parser-mysql</artifactId>
  <version>${project.version}</version>
</dependency>
```
• Obtain AST

```java
CacheOption cacheOption = new CacheOption(128, 1024L);
SQLParserEngine parserEngine = new SQLParserEngine("MySQL", cacheOption);
ParseASTNode parseASTNode = parserEngine.parse(sql, useCache);
```

• Obtain SQLStatement

```java
CacheOption cacheOption = new CacheOption(128, 1024L);
SQLParserEngine parserEngine = new SQLParserEngine("MySQL", cacheOption);
ParseASTNode parseASTNode = parserEngine.parse(sql, useCache);
SQLVisitorEngine sqlVisitorEngine = new SQLVisitorEngine(sql, "STATEMENT", useCache, new Properties());
SQLStatement sqlStatement = sqlVisitorEngine.visit(parseASTNode);
```

• SQL Formatting

```java
new SQLFormatEngine(databaseType, cacheOption).format(sql, useCache, props);
```

Example:
<table>
<thead>
<tr>
<th>Original SQL</th>
<th>Formatted SQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>select a+1 as b, name n from table1 join table2 where id=1 and name= lulu</td>
<td>SELECT a + 1 AS b, name n FROM table1 JOIN table2 WHERE id = 1 and name = lulu</td>
</tr>
<tr>
<td>select id, name, age, sex, ss, yy from table1 where id=1;</td>
<td>SELECT id, name, age, sex, ss, yy FROM table1 WHERE id = 1;</td>
</tr>
<tr>
<td>select id, name, age, count(*) as n, (select id, name, age from table2 where id=2) as sid, yyyy from table1 where id=1;</td>
<td>SELECT id, name, age, COUNT(*) AS n, (SELECT id, name, age FROM table2 WHERE id = 2) AS sid FROM table1 WHERE id = 1;</td>
</tr>
<tr>
<td>select id, name, age, sex, ss, yy from table1 where id=1 and name=1 and a=1 and b=2 and c=4 and d=3;</td>
<td>SELECT id, name, age, sex, ss, yy FROM table1 WHERE id = 1 and name = 1 and a = 1 and b = 2 and c = 4 and d = 3;</td>
</tr>
<tr>
<td>ALTER TABLE t_order ADD column4 DATE, ADD column5 DATETIME, engine ss max_rows 10, min_rows 2, ADD column6 TIMESTAMP, ADD column7 TIME;</td>
<td>ALTER TABLE t_order ADD column4 DATE, ADD column5 DATETIME, ENGINE ss MAX_ROWS 10, MIN_ROWS 2, ADD column6 TIMESTAMP, ADD column7 TIME;</td>
</tr>
<tr>
<td>CREATE TABLE IF NOT EXISTS runoob_tbl (runoob_id INT UNSIGNED AUTO_INCREMENT, runoob_title VARCHAR(100) NOT NULL, runoob_author VARCHAR(40) NOT NULL, runoob_test NATIONAL CHAR(40), submission_date DATE, PRIMARY KEY (runoob_id)) ENGINE=InnoDB DEFAULT CHARSET=utf8;</td>
<td>CREATE TABLE IF NOT EXISTS runoob_tbl (runoob_id INT UNSIGNED AUTO_INCREMENT, runoob_title VARCHAR(100) NOT NULL, runoob_author VARCHAR(40) NOT NULL, runoob_test NATIONAL CHAR(40), submission_date DATE, PRIMARY KEY (runoob_id)) ENGINE=InnoDB DEFAULT CHARSET=utf8;</td>
</tr>
<tr>
<td>INSERT INTO t_order_item(order_id, user_id, status, creation_date) SELECT order_id, user_id, status FROM t_order WHERE order_id=1;</td>
<td>INSERT INTO t_order SET order_id = 1, user_id = 1, status = convert(to_base64(aes_encrypt(1, 'key')) USING utf8) ON DUPLICATE KEY UPDATE status = VALUES(status);</td>
</tr>
<tr>
<td>INSERT INTO t_order SET order_id = 1, user_id = 1, status = convert(to_base64(aes_encrypt(1, 'key')) USING utf8) ON DUPLICATE KEY UPDATE status = VALUES(status);</td>
<td>INSERT INTO t_order (order_id, user_id, status) SELECT order_id, user_id, status FROM t_order WHERE order_id = 1;</td>
</tr>
</tbody>
</table>

12.4. Sharding 522
12.4.8 Route Engine

Sharding strategies for databases and tables are matched based on the parsing context, and routing paths are generated. SQL with shard keys can be divided into the single-shard router (the shard key operator is equal), multi-shard router (the shard key operator is IN), and range router (the shard key operator is BETWEEN). SQL that does not carry shard keys adopts broadcast routing.

Sharding strategies can usually be configured either by the built-in database or by the user. The built-in database scheme is relatively simple, and the built-in sharding strategy can be roughly divided into mantissa modulo, hash, range, label, time, etc.

The sharding strategies configured by the user are more flexible. You can customize the compound sharding strategy based on the user’s requirements. If it is used with automatic data migration, users do not need to work on the sharding strategies.

Sharding and data balancing can be automatically achieved by the middle layer of the database, and distributed databases can achieve elastic scalability. In the planning of ShardingSphere, the elastic scaling function will be available at V4.x.

Sharding Route

The scenario that is routed based on shard keys is divided into three types: direct route, standard route, and Cartesian route.

Direct Route

The requirement for direct route is relatively harsh. It needs to be sharded by Hint (using HintAPI to specify routes to databases and tables), and it can avoid SQL parsing and subsequent result merge on the premise of having database shards but not table shards.

Therefore, it is the most compatible one and can execute any SQL in complex scenarios including sub-queries and custom functions. The direct route can also be used when shard keys are not in SQL. For example, set the key for database sharding to 3,

```java
hintManager.setDatabaseShardingValue(3);
```

If the routing algorithm is value % 2, when a logical database `t_order` corresponds to two physical databases `t_order_0` and `t_order_1`, the SQL will be executed on `t_order_1` after routing. The following is a sample code using the API.

```java
String sql = "SELECT * FROM t_order";
try {
    HintManager hintManager = HintManager.getInstance();
    Connection conn = dataSource.getConnection();
    PreparedStatement pstmt = conn.prepareStatement(sql)) {
        hintManager.setDatabaseShardingValue(3);
        try (ResultSet rs = pstmt.executeQuery()) {
            while (rs.next()) {
```

12.4. Sharding
Standard Route

The standard route is the most recommended sharding method, and it is applicable to SQL that does not contain an associated query or only contains the associated query between binding tables.

When the sharding operator is equal, the routing result will fall into a single database (table). When the sharding operator is BETWEEN or IN, the routing result will not necessarily fall into a unique database (table).

Therefore, logical SQL may eventually be split into multiple real SQL to be executed. For example, if the data sharding is carried out according to the odd and even numbers of order_id, the SQL for a single table query is as follows:

```sql
SELECT * FROM t_order WHERE order_id IN (1, 2);
```

Then the routing result should be:

```sql
SELECT * FROM t_order_0 WHERE order_id IN (1, 2);
SELECT * FROM t_order_1 WHERE order_id IN (1, 2);
```

An associated query for a binding table is as complex as a single table query and they have the same performance. For example, if the SQL of an associated query that contains binding tables is as follows:

```sql
SELECT * FROM t_order o JOIN t_order_item i ON o.order_id=i.order_id WHERE order_id IN (1, 2);
```

Then the routing result should be:

```sql
SELECT * FROM t_order_0 o JOIN t_order_item_0 i ON o.order_id=i.order_id WHERE order_id IN (1, 2);
SELECT * FROM t_order_1 o JOIN t_order_item_1 i ON o.order_id=i.order_id WHERE order_id IN (1, 2);
```

As you can see, the number of SQL splits is consistent with that of a single table.
Apache ShardingSphere document

**Cartesian Route**

The Cartesian route is the most complex one because it cannot locate sharding rules according to the relationship between binding tables, so associated queries between unbound tables need to be disassembled and executed as cartesian product combinations. If the SQL in the previous example was not configured with binding table relationships, the routing result would be:

```sql
SELECT * FROM t_order_0 o JOIN t_order_item_0 i ON o.order_id=i.order_id WHERE order_id IN (1, 2);
SELECT * FROM t_order_0 o JOIN t_order_item_1 i ON o.order_id=i.order_id WHERE order_id IN (1, 2);
SELECT * FROM t_order_1 o JOIN t_order_item_0 i ON o.order_id=i.order_id WHERE order_id IN (1, 2);
SELECT * FROM t_order_1 o JOIN t_order_item_1 i ON o.order_id=i.order_id WHERE order_id IN (1, 2);
```

The Cartesian route query has low performance, so think carefully when you use it.

**Broadcast Route**

For SQL that does not carry shard keys, broadcast routes are used. According to the SQL type, it can be further divided into five types: full database and table route, full database route, full instance route, unicast route, and block route.

**Full database and table route**

The full database table route is used to handle operations on all real tables related to its logical tables in the database, including DQL and DML without shard keys, as well as DDL, etc. For example:

```sql
SELECT * FROM t_order WHERE good_prority IN (1, 10);
```

All tables in all databases will be traversed, matching logical tables and real table names one by one. The table that can be matched will be executed. The routing result would be:

```sql
SELECT * FROM t_order_0 WHERE good_prority IN (1, 10);
SELECT * FROM t_order_1 WHERE good_prority IN (1, 10);
SELECT * FROM t_order_2 WHERE good_prority IN (1, 10);
SELECT * FROM t_order_3 WHERE good_prority IN (1, 10);
```
Full database route

The full database route is used to handle operations on the database, including database management commands of type SET for database settings and transaction control statements such as TCL.

In this case, all real database matching names are traversed based on the logical database name, and the command is executed in the real database. For example:

```
SET autocommit=0;
```

If the command is executed in `t_order`, `t_order` which has two real databases, it is actually executed on both `t_order_0` and `t_order_1`.

Full instance route

Full instance route is used for DCL operations, and authorized statements are used for database instances.

No matter how many schemas are contained in an instance, each database instance is executed only once. For example:

```
CREATE USER customer@127.0.0.1 identified BY '123';
```

This command will be executed on all real database instances to ensure that users can access each instance.

Unicast Route

The unicast route is used to obtain the information of a real table. It only needs to obtain data from any real table in any database. For example:

```
DESCRIBE t_order;
```

t_order_0 and t_order_1, the two real tables of t_order, have the same description structure, so this command is executed only once on any real table.

Block Route

Block route is used to block SQL operations on the database, for example:

```
USE order_db;
```

This command will not be executed in a real database because ShardingSphere uses the logical Schema and there is no need to send the Schema shift command to the database.

The overall structure of the routing engine is as follows.
12.4.9 Rewrite Engine

SQL written by engineers for logical databases and tables cannot be directly executed in real databases. SQL rewriting is used to rewrite logical SQL into SQL that can be executed correctly in real databases. It includes rewriting for correctness and rewriting for optimization.

Rewriting for Correctness

In a scenario with table shards, you need to rewrite the logical table name in the table shards configuration to the real table name obtained after routing.

Only database shards do not require rewriting table names. Additionally, it also includes column derivation and pagination information correction.

Identifier Rewriting

The identifiers that need to be overwritten include table names, index names, and Schema names. Rewriting table names is the process of finding the location of the logical table in the original SQL and rewriting it into a real table.

Table name rewriting is a typical scenario that requires SQL parsing. For example, if logical SQL is:
Assume that the SQL is configured with the shard key `order_id` and `order_id=1`, it will be routed to shard table 1. Then the rewritten SQL should be:

```sql
SELECT order_id FROM t_order_1 WHERE order_id=1;
```

In the simplest SQL scenario, it doesn’t seem to matter whether or not the SQL is parsed into an abstract syntax tree. SQL can be rewritten correctly only by finding and replacing strings. However, it is impossible to achieve the same effect in the following scenarios.

```sql
SELECT order_id FROM t_order WHERE order_id=1 AND remarks=' t_order xxx';
```

The correct rewritten SQL would be:

```sql
SELECT order_id FROM t_order_1 WHERE order_id=1 AND remarks=' t_order xxx';
```

Instead of:

```sql
SELECT order_id FROM t_order_1 WHERE order_id=1 AND remarks=' t_order_1 xxx';
```

Because there may be characters similar to the table name, you cannot rewrite SQL simply by replacing strings.

Let’s look at a more complex scenario:

```sql
SELECT t_order.order_id FROM t_order WHERE t_order.order_id=1 AND remarks=' t_order xxx';
```

The above SQL uses the table name as an identifier of the field, so it needs to be modified when SQL is rewritten:

```sql
SELECT t_order_1.order_id FROM t_order_1 WHERE t_order_1.order_id=1 AND remarks=' t_order xxx';
```

If a table alias is defined in SQL, the alias does not need to be modified, even if it is the same as the table name. For example:

```sql
SELECT t_order.order_id FROM t_order AS t_order WHERE t_order.order_id=1 AND remarks=' t_order xxx';
```

Rewriting the table name is enough for SQL rewriting.

```sql
SELECT t_order_1.order_id FROM t_order_1 AS t_order WHERE t_order_1.order_id=1 AND remarks=' t_order xxx';
```

The index name is another identifier that can be rewritten. In some databases (such as MySQL and SQLServer), indexes are created in the dimension of tables.
Indexes in different tables can have the same name. In other databases (such as PostgreSQL and Oracle), indexes are created in the dimension of databases, and even indexes on different tables should have unique names.

In ShardingSphere, schemas are managed in the same way as tables. Logical Schemas are used to manage a set of data sources.

Therefore, ShardingSphere needs to replace the logical Schema written by the user in SQL with the real database Schema.

Currently, ShardingSphere does not support the use of Schema in DQL and DML statements. It only supports the use of Schema in database management statements. For example:

```sql
SHOW COLUMNS FROM t_order FROM order_ds;
```

Schema rewriting refers to the rewriting of a logical Schema using unicast routing to a correct and real Schema that is randomly found.

**Column Derivation**

There are two cases that need to complement columns in a query statement. In the first case, ShardingSphere needs to get the data during the result merge, but the data is not returned by the queried SQL.

In this case, it mainly applies to GROUP BY and ORDER BY. When merging the results, you need to group and order the field items according to GROUP BY and ORDER BY, but if the original SQL does not contain grouping or ordering items in the selections, you need to rewrite the original SQL. Let’s look at a scenario where the original SQL has the required information for result merge.

```sql
SELECT order_id, user_id FROM t_order ORDER BY user_id;
```

Since `user_id` is used for sorting, the data of `user_id` needs to be retrieved in the result merge. And the above SQL can obtain the data of `user_id`, so there is no need to add columns.

If the selection does not contain the columns required to merge the results, you need to fill the columns, as in the following SQL:

```sql
SELECT order_id FROM t_order ORDER BY user_id;
```

Since the original SQL does not contain the `user_id` required in the result merge, you need to fill in and rewrite the SQL. Then SQL would be:

```sql
SELECT order_id, user_id AS ORDER_BY_DERIVED_0 FROM t_order ORDER BY user_id;
```

It should be noted that only missing columns are complemented instead of all columns. And SQL that contains `*` in the SELECT statement will also selectively complement columns based on the metadata information of the table. Here is a relatively complex column derivation scenario of SQL:

```sql
SELECT o.* FROM t_order o, t_order_item i WHERE o.order_id=i.order_id ORDER BY user_id, order_item_id;
```
We assume that only the table `t_order_item` contains the column `order_item_id`. According to the metadata information of the table, when the result is merged, the `user_id` in the ordering items exists on the table `t_order`, so there is no need to add columns. `order_item_id` is not in `t_order`, so column derivation is required. Then SQL would become:

```sql
SELECT o.*, order_item_id AS ORDER_BY_DERIVED_0 FROM t_order o, t_order_item i WHERE o.order_id=i.order_id ORDER BY user_id, order_item_id;
```

The second case of column derivation is the use of AVG aggregate functions. In distributed scenarios, using \((\text{avg}1 + \text{avg}2 + \text{avg}3)/3\) to calculate the average is incorrect and should be rewritten as \((\text{sum}1 + \text{sum}2 + \text{sum}3)/(\text{count}1 + \text{count}2 + \text{count}3)\). In this case, rewriting the SQL containing AVG to SUM and COUNT is required, and recalculating the average when the results are merged. For example:

```sql
SELECT AVG(price) FROM t_order WHERE user_id=1;
```

The above SQL should be rewritten as:

```sql
SELECT COUNT(price) AS AVG_DERIVED_COUNT_0, SUM(price) AS AVG_DERIVED_SUM_0 FROM t_order WHERE user_id=1;
```

Then you can calculate the average correctly by merging the results.

The last type of column derivation is the one that does not need to write the primary key field if the database auto-increment primary key is used during executing an INSERT SQL statement. However, the auto-increment primary key of the database cannot meet the unique primary key in distributed scenarios. Therefore, ShardingSphere provides the generation strategy of the distributed auto-increment primary key. Users can replace the existing auto-increment primary key transparently with the distributed auto-increment primary key without changing the existing code through column derivation. The generation strategy for distributed auto-increment primary keys is described below, and here only SQL rewriting is illustrated. For example, if the primary key of table `t_order` is `order_id`, the original SQL would be:

```sql
INSERT INTO t_order (`field1`, `field2`) VALUES (10, 1);
```

As you can see, the above SQL does not contain the auto-increment primary key, which requires the database itself to fill. After ShardingSphere is configured with the auto-increment primary key, SQL will be rewritten as:

```sql
INSERT INTO t_order (`field1`, `field2`, order_id) VALUES (10, 1, xxxxx);
```

The rewritten SQL will add column names of the primary key and auto-increment primary key values generated automatically at the end of the INSERT FIELD and INSERT VALUE. The xxxxx in the above SQL represents the auto-increment primary key value generated automatically.

If the INSERT SQL does not contain the column name of the table, ShardingSphere can also compare the number of parameters and the number of columns in the table meta information and automatically generate auto-increment primary keys. For example, the original SQL is:
The rewritten SQL will simply add the auto-increment primary key in the column order in which the primary key locates:

```
INSERT INTO t_order VALUES (xxxxx, 10, 1);
```

If you use placeholders to write SQL, you only need to rewrite the parameter list, not the SQL itself.

**Pagination Correction**

The scenario of acquiring pagination data from multiple databases is different from that of one single database. If every 10 pieces of data are taken as one page, the user wants to take the second page of data. It is not correct to acquire LIMIT 10, 10 under sharding situations, or take out the first 10 pieces of data according to sorting conditions after merging. For example, if SQL is:

```
SELECT score FROM t_score ORDER BY score DESC LIMIT 1, 2;
```

The following picture shows the pagination execution results without SQL rewriting.

As shown in the picture, if you want to acquire the second and the third piece of data sorted by score in both tables, and they are supposed to be 95 and 90.

Since executed SQL can only acquire the second and the third piece of data from each table, i.e., 90 and 80 from t_score_0, 85 and 75 from t_score_1. When merging results, it can only merge from 90, 80, 85 and 75 already acquired, so the right result cannot be acquired anyway.
The right way is to rewrite pagination conditions as \texttt{LIMIT 0, 3}, take out all the data from the first two pages and calculate the right data based on sorting conditions. The following picture shows the execution results of pagination after SQL rewrite.

The latter the offset position is, the lower the efficiency of using \texttt{LIMIT} pagination will be. There are many ways to avoid using \texttt{LIMIT} as pagination method, such as constructing a secondary index to the number of line records and line offsets or using the end ID of the last pagination data as a condition for the next query.

When revising pagination information, if the users use the placeholder to write SQL, they only need to rewrite the parameter list rather than SQL itself.

**Batch Split**

When using bulk inserted SQL, if the inserted data crosses shards, the SQL needs to be rewritten to prevent excess data from being written to the database.

The insertion operation differs from the query operation in that the query statement does not affect the data even if it uses the shard key that does not exist in the current shard. In contrast, insertion operations must remove excess shard keys. For example, see the following SQL:

\begin{verbatim}
INSERT INTO t_order (order_id, xxx) VALUES (1, 'xxx'), (2, 'xxx'), (3, 'xxx');
\end{verbatim}

If the database is still divided into two parts according to the odd and even number of order_id, this SQL will be executed after its table name is revised. Then, both shards will be written with the same record.
Though only the data that satisfies sharding conditions can be retrieved from the query statement, it is not reasonable for the schema to have excessive data. So SQL should be rewritten as:

```sql
INSERT INTO t_order_0 (order_id, xxx) VALUES (2, 'xxx');
INSERT INTO t_order_1 (order_id, xxx) VALUES (1, 'xxx'), (3, 'xxx');
```

IN query is similar to batch insertion, but IN operation will not lead to wrong data query result. Through rewriting IN query, the query performance can be further improved. See the following SQL:

```sql
SELECT * FROM t_order WHERE order_id IN (1, 2, 3);
```

The SQL is rewritten as:

```sql
SELECT * FROM t_order_0 WHERE order_id IN (2);
SELECT * FROM t_order_1 WHERE order_id IN (1, 3);
```

The query performance will be further improved. For now, ShardingSphere has not realized this rewrite strategy, so the current rewrite result is:

```sql
SELECT * FROM t_order_0 WHERE order_id IN (1, 2, 3);
SELECT * FROM t_order_1 WHERE order_id IN (1, 2, 3);
```

Though the execution result of SQL is right, it did not achieve the highest query efficiency.

**Rewriting for Optimization**

Its purpose is to effectively improve performance without influencing the correctness of the query. It can be divided into single node optimization and stream merger optimization.

**Single Node Optimization**

It refers to the optimization that stops the SQL rewrite from the route to the single node. After acquiring one route result, if it is routed to a single data node, there is no need to involve result merger, as well as rewrites such as column derivation and pagination information correction.

In particular, there is no need to read from the first piece of information, which reduces the pressure on the database to a large extent and saves meaningless consumption of the network bandwidth.

**Stream Merger Optimization**

It only adds ORDER BY and ordering items and sorting orders identical with grouping items to SQL that contains GROUP BY. And it is used to transfer memory merger to stream merger. Stream merger and memory merger will be explained in detail in the result merger section.

The overall structure of the rewrite engine is shown in the following picture.
12.4.10 Execute Engine

ShardingSphere uses an automated execution engine to safely and efficiently send the real SQL, which has been routed and rewritten, to the underlying data source for execution.

It does not simply send SQL directly to the data source for execution via JDBC, nor are execution requests placed directly into a thread pool for concurrent execution.

It focuses more on the creation of a balanced data source connection, the consumption generated by the memory usage, and the maximum utilization of the concurrency. The objective of the execution engine is to automatically balance resource control with execution efficiency.

Connection Mode

From the perspective of resource control, the connection number a business can make to the database should be limited. It can effectively prevent certain business operations from occupying excessive resources, exhausting database connection resources, and influencing the normal access of other businesses.

Especially when one database instance contains many sub-tables, a logical SQL that does not contain any shard key will produce a large number of real SQLs that fall into different tables in one database. If each real SQL takes an independent connection, a query will undoubtedly take up excessive resources.

From the perspective of execution efficiency, maintaining an independent database connection for each shard query can make more effective use of multi-thread to improve execution efficiency.
Creating a separate thread for each database connection allows I/O consumption to be processed in parallel. Maintaining a separate database connection for each shard also prevents premature loading of query result data into memory.

It is enough for independent database connections to maintain result set quotation and cursor position, and move the cursor when acquiring corresponding data.

Merging the result set by moving down its cursor is called the stream merger. It does not need to load all the query results into the memory, which can effectively save memory resources effectively and reduce the frequency of garbage collection.

If each shard query cannot be guaranteed to have an independent database connection, the current query result set needs to be loaded into memory before reusing the database connection to obtain the query result set of the next shard table. Therefore, though the stream merger can be used, it will also degenerate into the memory merger in this scenario.

On the one hand, we need to control and protect database connection resources; on the other hand, it is important to save middleware memory resources by adopting a better merging mode. How to deal with the relationship between the two is a problem that the ShardingSphere execution engine needs to solve. Specifically, if an SQL is sharded through the ShardingSphere, it needs to operate on 200 tables under a database instance. So, should we choose to create 200 connections in parallel, or one connection in sequence? How to choose between efficiency and resource control? For the above scenario, ShardingSphere provides a solution. It introduces the concept of Connection Mode, which is divided into MEMORY STRICTLY and CONNECTION STRICTLY.

**MEMORY STRICTLY Mode**

The prerequisite to using this mode is that ShardingSphere does not restrict the connection number of one operation. If the actual executed SQL needs to operate 200 tables in some database instance, it will create a new database connection for each table and deal with them concurrently through multi-thread to maximize the execution efficiency. When SQL meets the conditions, stream merger is preferred to avoid memory overflow or frequent garbage recycling.

**CONNECTION STRICTLY Mode**

The prerequisite to using this mode is that ShardingSphere strictly restricts the connection consumption number of one operation. If the SQL to be executed needs to operate 200 tables in a database instance, it will create one database connection and operate them serially. If shards exist in different databases, it will still adopt multi-thread operations for different databases, but with only one database connection being created for each operation in each database. It prevents the problem of consuming too many database connections for one request. The mode chooses memory merger all the time.

The MEMORY STRICTLY mode applies to OLAP operation and can increase the system throughput by removing database connection restrictions. It is also applicable to OLTP operation, which usually has shard keys and can be routed to a single shard. So it is a wise choice to control database connections strictly to make sure that database resources in an online system can be used by more applications.
**Automatic Execution Engine**

ShardingSphere initially leaves the decision of which mode to use up to the users and they can choose to use MEMORY STRICTLY mode or CONNECTION STRICTLY mode according to their actual business scenarios.

This solution gives users the right to choose, who must understand the pros and cons of the two modes and make a choice based on the requirements of the business scenarios. No doubt, it is not the best solution as it increases users’ learning and use costs.

This dichotomy solution, which leaves the switching of the two modes to static initialization, lacks flexibility. In practical scenarios, the routing result varies with SQL and placeholder indexes. This means that some operations may need to use memory merger, while others may prefer stream merger. Connection modes should not be set by the user before ShardingSphere is started, but should be determined dynamically based on the SQL and placeholder indexes scenarios.

In order to reduce the usage cost for users and achieve a dynamic connection mode, ShardingSphere has extracted the concept of the automatic execution engine to eliminate the connection mode concept internally. The user does not need to know what the MEMORY STRICTLY mode and CONNECTION STRICTLY mode are, but the execution engine automatically selects the best execution scheme according to the current scenario.

The automatic execution engine chooses the connection mode based on each SQL operation. For each SQL request, the automatic execution engine will do real-time calculations and evaluations according to its route result and execute the appropriate connection mode automatically to strike the optimal balance between resource control and efficiency. For the automatic execution engine, users only need to configure maxConnectionSizePerQuery, which represents the maximum connection number allowed by each database for one query.

The execution engine is divided into two phases: preparation and execution.

**Preparation Phrase**

As indicated by its name, this phrase is used to prepare the data to be executed. It can be divided into two steps: result set grouping and unit creation.

Result set grouping is the key to realizing the internal connection model concept. According to the configuration items of maxConnectionSizePerQuery, the execution engine will choose an appropriate connection mode based on the current route result.

Detailed steps are as follow:

1. Group SQL route results according to data source names.
2. As we can see in the following formula, users can acquire the SQL route result set to be executed by each database instance within the maxConnectionSizePerQuery permission range and calculate the optimal connection mode of this request.
Within the scope of the maxConnectionSizePerQuery allowed, when the request number that one connection needs to execute is more than 1, the current database connection cannot hold the corresponding data result set, so it must use memory merger. On the contrary, when the number equals 1, the current database connection can hold the corresponding data result set, and it can use stream merger.

Each connection mode selection is specific to each physical database. That is, if you route to more than one database in the same query, the connection mode of each database may not be the same, and they may be mixed. Users can use the route grouping result acquired from the last step to create the execution unit. When the data source uses technologies, such as the database connection pool, to control database connection numbers, there is a chance that a deadlock will occur if concurrency is not handled properly while retrieving database connections. As multiple requests wait for each other to release database connection resources, starvation occurs, causing the crossing deadlock.

For example, suppose that a query requires obtaining two database connections at a data source and routing queries to two sub-tables of the same database. It is possible that query A has obtained one database connection from this data source and is waiting to obtain another database connection.

Query B has also acquired a database connection at the data source and is also waiting for another database connection to be acquired. If the maximum number of connections allowed in the database connection pool is 2, then the two query requests will wait forever. The following diagram depicts a deadlock situation.
ShardingSphere synchronizes database connections to avoid deadlocks. When it creates the execution unit, it atomically obtains all the database connections required by the SQL request at one time, eliminating the possibility of obtaining partial resources in each query request.

Because the operation on the database is very frequent, locking a database connection each time when acquiring it will reduce the concurrency of ShardingSphere. Therefore, ShardingSphere has improved two aspects here:

1. Locking can be avoided and only one database connection needs to be obtained each time. Because under this circumstance, two requests waiting for each other will not happen, so there is no need for locking. Most OLTP operations use shard keys to route to the unique data node, which makes the system completely unlocked and further improves the concurrency efficiency. In addition to routing to a single shard, read/write-splitting also belongs to this category.

2. Locking resources only happens in MEMORY_STRICTLY mode. When using CONNECTION_STRICTLY mode, all the query result sets will release database connection resources after loading them to the memory, so deadlock wait will not appear.
Execution Phrase

This stage is used to actually execute SQL and is divided into two steps: group execution and merger result generation.

Group execution can distribute execution unit groups generated in the preparation phase to the underlying concurrency engine and send events for each key step during the execution process, such as starting, successful and failed execution events. The execution engine only focuses on sending events rather than subscribers to the event. Other ShardingSphere modules, such as distributed transactions, call linked tracing and so on, will subscribe to the events of interest and process them accordingly.

ShardingSphere generates memory merger result sets or stream merger result sets through the connection mode acquired in the preparation phase. And then it passes the result set to the result merger engine for the next step.

The overall structure of the execution engine is divided as shown below.
12.4.11 Merger Engine

Result merger refers to merging multi-data result sets acquired from all the data nodes as one result set and returning it to the requesting client correctly.

The result merger supported by ShardingSphere can be divided into five functional types: traversal, order-by, group-by, pagination and aggregation, which are combined rather than mutually exclusive. From the perspective of structure, it can be divided into stream merger, memory merger and decorator merger, among which stream merger and memory merger are mutually exclusive, and decorator merger can be further processed based on stream merger and memory merger.

Since the result set is returned from the database one by one instead of being loaded to the memory all at a time, the method of merging the result sets returned from the database can greatly reduce memory consumption and is the preferred method of merging.

Stream merger means that each time the data is obtained from the result set is able to return the correct single piece of data line by line. It is the best fit with the native method of returning the result set of the database. Traversal, order-by, and stream group-by are all examples of the stream merger.

Memory merger needs to traverse all the data in the result set and store it in the memory first. After unified grouping, ordering, aggregation and other calculations, the data is packaged into the data result set accessed one by one and returned.

Decorator merger merges and reinforces all the result sets function uniformly. Currently, decorator merger has two types: pagination merger and aggregation merger.

**Traversal Merger**

As the simplest merger method, traversal merger only requires the combination of multiple data result sets into a one-way linked table. After traversing current data result sets in the linked table, it only needs to move the elements of the linked table back one bit and continue traversing the next data result set.

**Order-by Merger**

Because there is an ORDER BY statement in SQL, each data result has its own order. So it only needs to sort data value that the result set cursor currently points to, which is equal to sorting multiple ordered arrays. Therefore, order-by merger is the most suitable sorting algorithm in this scenario.

When merging ordered queries, ShardingSphere will compare current data values in each result set (which is realized by the Java Comparable interface) and put them into the priority queue. Each time when acquiring the next piece of data, it only needs to move down the result set cursor at the top of the queue, reenter the priority order according to the new cursor and relocate its own position.

Here is an instance to explain ShardingSphere’s order-by merger. The following picture is an illustration of ordering by the score. Data result sets returned by 3 tables are shown in the example and each of them has already been ordered according to the score, but there is no order between the 3 data result sets. Order the data value that the result set cursor currently points to in these 3 result sets. Then put them into the priority queue. The first data value of t_score_0 is the biggest, followed by that
of `t_score_2` and `t_score_1` in sequence. Thus, the priority queue is ordered by the sequence of `t_score_0`, `t_score_2` and `t_score_1`.

The following diagram illustrates how the order-by merger works when using next call. We can see from the diagram that when using the `next` call, `t_score_0` at the first of the queue will be popped out. After returning the data value currently pointed by the cursor (i.e., 100) to the requesting client, the cursor will be moved down and `t_score_0` will be put back into the queue.

While the priority queue will also be ordered according to the `t_score_0` data value (90 here) pointed by the cursor of the current data result set. According to the current value, `t_score_0` is at the end of the queue, and the data result set of `t_score_2`, originally in the second place of the queue, automatically moves to the first place of the queue.

In the second `next` call, `t_score_2` in the first place is popped out. Its value pointed by the cursor of the data result set is returned to the client end, with its cursor moved down to rejoin the queue, and the following will be the same way. If there is no data in the result set, it will not rejoin the queue.
It can be seen that when data in each result set is ordered, but multiple result sets are disordered, ShardingSphere can still order them with no need to upload all the data to the memory. In the stream merger method, each `next` operation only acquires the right piece of data each time, which saves memory consumption to a large extent.

On the other hand, the order-by merger has maintained the orderliness on the horizontal axis and vertical axis of the data result set. Naturally ordered, the vertical axis refers to each data result set itself, which is acquired by SQL with `ORDER BY`. The horizontal axis refers to the current value pointed by each data result set, and its order needs to be maintained by the priority queue. Each time when the current cursor moves down, it requires putting the result set in the priority order again, which means only the cursor of the first data result set can be moved down.

**Group-by Merger**

Group-by merger is the most complex one and can be divided into stream group-by merger and memory group-by merger. Stream group-by merger requires that the SQL’s ordering items must be consistent with the field and ordering types (ASC or DESC) of the group-by item; otherwise, data correctness can only be guaranteed by memory merger.

For instance, if it is sharded based on subject, the table structure contains the examinees’ name (to simplify, name repetition is not taken into consideration) and score. The following SQL is used to acquire each examinee’s total score:

```sql
SELECT name, SUM(score) FROM t_score GROUP BY name ORDER BY name;
```
When order-by item and group-by item are totally consistent, the data obtained is continuous. The data required by group-by is all stored in the data value that the data result set cursor currently points to. Thus, stream group-by merger can be used, as illustrated by the diagram:

The merging logic is similar to that of order-by merger. The following picture shows how the stream group-by merger works in the next call.
We can see from the picture that, in the first `next` call, `t_score_java` in the first place will be popped out of the queue, along with other result set data having the same grouping value of “Jerry”. After acquiring all the students’ scores with the name of “Jerry”, the accumulation operation will proceed. Hence, after the first `next` call is finished, the result set acquired is the sum of Jerry’s scores. At the same time, all the cursors in data result sets will be moved down to a different data value next to “Jerry” and reordered according to the current result set value. Thus, the data that contains the second name “John” will be put at the beginning of the queue.

Stream group-by merger is different from order-by merger only in two aspects:

1. It will take out all the data with the same group item from multiple data result sets at once.

2. It carried out the aggregation calculation according to the aggregation function type.

For the inconsistency between the grouping item and ordering item, it requires uploading all the data to the memory to group and aggregate, since the relevant data value needed to acquire group information is not continuous, and stream merger is not available. For example, acquire each examinee’s total score through the following SQL and order them from the highest to the lowest:

```
SELECT name, SUM(score) FROM t_score GROUP BY name ORDER BY score DESC;
```

Then, stream merger is not able to use, for the data taken out from each result set is the same as the original data of the order-by merger diagram in the upper half part structure.

When SQL only contains the group-by statement, according to different database implementations, its sorting order may not be the same as the group order. The lack of an ordering statement indicates the order is not important in this SQL. Therefore, through the optimization of SQL rewriting, Sharding-
Sphere can automatically add the ordering item the same as the grouping item, converting it from the memory merger that consumes memory to the stream merger.

**Aggregation Merger**

Whether it is stream group-by merger or memory group-by merger, they process the aggregation function in the same way. In addition to grouped SQL, ungrouped SQL can also use aggregate functions. Therefore, aggregation merger is an additional merging ability based on what has been introduced above, i.e., the decorator mode. The aggregation function can be categorized into three types: comparison, sum and average.

The comparison aggregation function refers to MAX and MIN. They need to compare all the result set data of each group and simply return the maximum or minimum value.

The sum aggregation function refers to SUM and COUNT. They need to sum up all the result set data of each group.

The average aggregation function refers only to AVG. It must be calculated through SUM and COUNT rewritten by SQL, which has been mentioned in the SQL rewriting section.

**Pagination Merger**

All the merger types above can be paginated. Pagination is the decorator added to other kinds of mergers. ShardingSphere strengthens its ability to paginate the data result set through decorator mode. The pagination merger is responsible for filtering unnecessary data.

ShardingSphere’s pagination function can be misleading to users in that they may think it will take a large amount of memory. In distributed scenarios, it can only guarantee the data correctness by rewriting LIMIT 10000000, 10 to LIMIT 0, 10000010. Users can easily misunderstand that ShardingSphere uploads a large amount of meaningless data to the memory and has the risk of memory overflow. Actually, it can be known from the principle of stream merger that only memory group-by merger will upload all the data to the memory. Generally speaking, SQL used for OLAP grouping, is often applied to massive calculations or small result generation, and it won’t generate vast result data. Except for memory group-by merger, other scenarios all use stream merger to acquire data result set. So ShardingSphere would skip unnecessary data through the next call method in the result set, rather than storing it in the memory.

But it should be noted that pagination with LIMIT is not the best practice, because a large amount of data still needs to be transmitted to ShardingSphere’s memory space for ordering. LIMIT cannot query data by index, so paginating with ID is a better solution if ID continuity can be guaranteed. For example:

```sql
SELECT * FROM t_order WHERE id > 100000 AND id <= 100010 ORDER BY id;
```

Or query the next page through the ID of the last query result, for example:

```sql
SELECT * FROM t_order WHERE id > 10000000 LIMIT 10;
```
The overall structure of the merger engine is shown in the following diagram:

12.5 Transaction

12.5.1 Navigation

This chapter mainly introduces the principles of the distributed transactions:

- 2PC transaction with XA
- BASE transaction with Seata

12.5.2 XA Transaction

XA\text{ShardingSphereTransactionManager} is XA transaction manager of Apache ShardingSphere. Its main responsibility is manage and adapt multiple data sources, and sent corresponding transactions to concrete XA transaction manager.
Transaction Begin

When receiving set autoCommit=0 from client, XAShardingSphereTransactionManager will use XA transaction managers to start overall XA transactions, which is marked by XID.

Execute actual sharding SQL

After XAShardingSphereTransactionManager register the corresponding XAResource to the current XA transaction, transaction manager will send XAResource.start command to databases. After databases received XAResource.end command, all SQL operator will mark as XA transaction.

For example:

```java
XAResource1.start                   ## execute in the enlist phase
statement.execute("sql1");
statement.execute("sql2");
XAResource1.end                     ## execute in the commit phase
```

sql1 and sql2 in example will be marked as XA transaction.
**Commit or Rollback**

After `XAShardingSphereTransactionManager` receives the commit command in the access, it will delegate it to the actual XA manager. It will collect all the registered XAResource in the thread, before sending `XAResource.end` to mark the boundary for the XA transaction. Then it will send prepare command one by one to collect votes from XAResource. If all the XAResource feedback is OK, it will send commit command to finally finish it; If there is any No XAResource feedback, it will send rollback command to roll back. After sending the commit command, all XAResource exceptions will be submitted again according to the recovery log to ensure the atomicity and high consistency.

For example:

<table>
<thead>
<tr>
<th>XAResource1.prepare</th>
<th>## ack: yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>XAResource2.prepare</td>
<td>## ack: yes</td>
</tr>
<tr>
<td>XAResource1.commit</td>
<td></td>
</tr>
<tr>
<td>XAResource2.commit</td>
<td></td>
</tr>
<tr>
<td>XAResource1.prepare</td>
<td>## ack: yes</td>
</tr>
<tr>
<td>XAResource2.prepare</td>
<td>## ack: no</td>
</tr>
<tr>
<td>XAResource1.rollback</td>
<td></td>
</tr>
<tr>
<td>XAResource2.rollback</td>
<td></td>
</tr>
</tbody>
</table>

### 12.5.3 Seata BASE transaction

When integrating Seata AT transaction, we need to integrate TM, RM and TC component into ShardingSphere transaction manager. Seata have proxied `DataSource` interface in order to RPC with TC. Similarly, Apache ShardingSphere faced to `DataSource` interface to aggregate data sources too. After Seata `DataSource` encapsulation, it is easy to put Seata AT transaction into Apache ShardingSphere sharding ecosystem.
Init Seata Engine

When an application containing `ShardingSphereTransactionBaseSeataAT` startup, the user-configured `DataSource` will be wrapped into seata `DataSourceProxy` through `seata.conf`, then registered into RM.

Transaction Begin

TM controls the boundaries of global transactions. TM obtains the global transaction ID by sending Begin instructions to TC. All branch transactions participate in the global transaction through this global transaction ID. The context of the global transaction ID will be stored in the thread local variable.

Execute actual sharding SQL

Actual SQL in Seata global transaction will be intercepted to generate undo snapshots by RM and sends participate instructions to TC to join global transaction. Since actual sharding SQLs executed in multi-threads, global transaction context should transfer from main thread to child thread, which is exactly the same as context transfer between services.
**Commit or Rollback**

When submitting a seata transaction, TM sends TC the commit and rollback instructions of the global transaction. TC coordinates all branch transactions for commit and rollback according to the global transaction ID.

**12.6 Data Migration**

**12.6.1 Explanation**

The current data migration solution uses a completely new database cluster as the migration target. This implementation has the following advantages:

1. No impact on the original data during migration.
2. No risk in case of migration failure.
3. Freedom from sharding strategy limitations.

The implementation has the following disadvantages:

1. Redundant servers can exist for a certain period of time.
2. All data needs to be moved.

A single data migration mainly consists of the following phases:

1. Preparation.
2. Stock data migration.
3. The synchronization of incremental data.
4. Traffic switching.
12.6.2 Execution Stage Explained

Preparation

In the preparation stage, the data migration module verifies data source connectivity and permissions, counts stock data statistics, records the log and finally shards the tasks according to data volume and parallelism set by the users.

Stock data migration

Execute the stock data migration tasks that have been sharded during preparation stage. The stock migration stage uses JDBC queries to read data directly from the source and write into the target based on the sharding rules and other configurations.

The Synchronization of incremental data

Since the duration of stock data migration depends on factors such as data volume and parallelism, it is necessary to synchronize the data added to the business operations during this period. Different databases differ in technical details, but in general they are all based on replication protocols or WAL logs to achieve the capture of changed data.

- MySQL: subscribe and parse binlog.
- PostgreSQL: uses official logical replication test_decoding.

The incremental data captured is also written into the new data nodes by the data migration modules. When synchronization of incremental data is completed (the incremental data flow is not interrupted since the business system is still in function), you can then move to the traffic switching stage.

Traffic Switching

During this stage, there may be a read-only period of time, where data in the source data nodes is allowed to be in static mode for a short period of time to ensure that the incremental synchronization can be fully completed. Users can set this by shifting the database to read-only status or by controlling the traffic flow generated from the source.

The length of this read-only window depends on whether users need to perform consistency checks on the data and the exact amount of data in this scenario. Consistency check is an independent task. It supports separate start/stop and breakpoint resume.

Once confirmed, the data migration is complete. Users can then switch the read traffic or write traffic to Apache ShardingSphere.
12.7 Encryption

Apache ShardingSphere parses the SQL entered by users and rewrites the SQL according to the encryption rules provided by users.

When a user queries data, it only retrieves ciphertext data from the database, decrypts it, and finally returns the decrypted source data to the user. Apache ShardingSphere achieves a transparent and automatic data encryption process. Users can use encrypted data as normal data without paying attention to the implementation details of data encryption.

12.7.1 Overall Architecture

The encrypted module intercepts the SQL initiated by the user and parses and understands the SQL behavior through the SQL syntactic parser. Then it finds out the fields to be encrypted and the encryption and decryption algorithm according to the encryption rules introduced by the user and interacts with the underlying database.

Apache ShardingSphere will encrypt the plaintext requested by users and store it in the underlying database. When the user queries, the ciphertext is extracted from the database, decrypted, and re-
Apache ShardingSphere document

12.7.2 Encryption Rules

Before explaining the whole process, we need to understand the encryption rules and configuration. Encryption configuration is mainly divided into three parts: data source configuration, encryptor configuration, encryption table configuration, as shown in the figure below:

Data source configuration: the configuration of the data source.

Encryptor configuration: refers to the encryption algorithm used for encryption and decryption. Currently, ShardingSphere has three built-in encryption and decryption algorithms: AES, MD5 and RC4. Users can also implement a set of encryption and decryption algorithms by implementing the interfaces provided by ShardingSphere.

Encryption table configuration: it is used to tell ShardingSphere which column in the data table is used to store ciphertext data (cipherColumn), and which column the user would like to use for SQL writing (logicColumn).

What does it mean by “which column the user would like to use for SQL writing (logicColumn)”?

We have to know first why the encrypted module exists. The goal of the encrypted module is to shield the underlying data encryption process, which means we don’t want users to know how data is encrypted and decrypted, and how to store ciphertext data into cipherColumn. In other words, we don’t want users to know there is a cipherColumn or how they are used. Therefore, we need to provide the user with a conceptual column...
that can be separated from the real column in the underlying database. It may or may not be a real column in the database table so that users can change the column names of cipherColumn of the underlying database at will. The only thing we have to ensure is that the user’s SQL is written towards the logical column, and the correct mapping relation between logicColumn and cipherColumn can be seen in the encryption rules.

Query attribute configuration: if both plaintext and ciphertext data are stored in the underlying database table, this attribute can be used to determine whether to query the plaintext data in the database table and return it directly, or query the ciphertext data and return it after decryption through Apache ShardingSphere. This attribute can be configured at the table level and the entire rule level. The table-level has the highest priority.

### 12.7.3 Encryption Process

For example, if there is a table named `t_user` in the database, and they’re two fields in the table: `pwd_cipher` for storing ciphertext data, and logicColumn is defined as `pwd`, then users should write SQL for logicColumn, that is `INSERT INTO t_user SET pwd = '123'`. Apache ShardingSphere receives the SQL and finds that the `pwd` is the logicColumn based on the encryption configuration provided by the user. Therefore, it encrypts the logical column and its corresponding plaintext data.

Apache ShardingSphere transforms the column names and data encryption mapping between the logical columns facing users and cipher columns facing the underlying database. As shown in the figure below:

---

The user’s SQL is separated from the underlying data table structure according to the encryption rules.
provided by the user so that the user’s SQL writing does not depend on the real database table structure. The connection, mapping, and transformation between the user and the underlying database are handled by Apache ShardingSphere.

The picture below shows the processing flow and conversion logic when the encryption module is used to add, delete, change and check, as shown in the figure below.

### Detailed Solution

After understanding Apache ShardingSphere’s encryption process, you can combine the encryption configuration and encryption process according to your scenario. The entire design & development was conceived to address the pain points encountered in business scenarios. So, how to use Apache ShardingSphere to meet the business requirements mentioned before?

Business scenario analysis: the newly launched business is relatively simple because it starts from scratch and there’s no need to clean up historical data.

Solution description: after selecting the appropriate encryption algorithm, such as AES, you only need to configure the logical column (write SQL for users) and the ciphertext column (the data table stores the ciphertext data). The logical columns and ciphertext columns can also be different. The following configurations are recommended (in YAML format):

```yaml
- !ENCRYPT
  encryptors:
    aes_encryptor:
```
With the above configuration, Apache ShardingSphere only needs to convert logicColumn, cipherColumn, and assistedQueryColumn. The underlying data table does not store plaintext, and only ciphertext is stored, which is also the requirement of the security audit. The overall processing flow is shown in the figure below:

![Diagram showing the encryption process with plaintext data being encrypted and converted to ciphertext data.](image-url)
The advantages of Middleware encryption service

1. Automatic and transparent data encryption process. Encryption implementation details are no longer a concern for users.
2. It provides a variety of built-in and third-party (AKS) encryption algorithms, which are available through simple configurations.
3. It provides an encryption algorithm API interface. Users can implement the interface to use a custom encryption algorithm for data encryption.
4. It can switch among different encryption algorithms.

Solution

Apache ShardingSphere provides an encryption algorithm for data encryption, namely EncryptAlgorithm.

On the one hand, Apache ShardingSphere provides users with built-in implementation classes for encryption and decryption, which are available through configurations by users.

On the other hand, in order to be applicable to different scenarios, we also opened the encryption and decryption interfaces, and users can provide specific implementation classes according to these two types of interfaces.

After simple configuration, Apache ShardingSphere can call user-defined encryption and decryption schemes for data encryption.

12.7.4 EncryptAlgorithm

The solution provides two methods, encrypt() and decrypt(), to encrypt or decrypt data. When users perform INSERT, DELETE and UPDATE operations, ShardingSphere will parse, rewrite and route SQL according to the configuration.

It will also use encrypt() to encrypt data and store them in the database. When using SELECT, they will decrypt sensitive data from the database with decrypt() and finally return the original data to users.

Currently, Apache ShardingSphere provides three types of implementations for this kind of encryption solution, including MD5 (irreversible), AES (reversible) and RC4 (reversible), which can be used after configuration.
12.8 Mask

Apache ShardingSphere achieves the desensitization of the original data by parsing the SQL queried by users and masking the SQL execution results according to the desensitization rules provided by users.

12.8.1 Overall Architecture

The desensitization module intercepts the SQL initiated by the user, analyzes and executes it through the SQL syntax parser. It then masks the query results by finding out the fields to be desensitized and the desensitization algorithm to be used according to the rules passed specified by the user, and returns to the client.

12.8.2 Mask Rules

Before explaining the whole process in detail, we need to first understand the desensitization rules and configuration, which is the basis of understanding the whole process.

Desensitization configuration is mainly divided into three parts: data source configuration, desensitization algorithm configuration, desensitization table configuration:
**Datasource configuration:** the configuration of the data source.

**Mask algorithm configuration:** currently, ShardingSphere has a variety of built-in desensitization algorithms: MD5, KEEP_FIRST_N_LAST_M, KEEP_FROM_X_TO_Y, MASK_FIRST_N_LAST_M, MASK_FROM_X_TO_Y, MASK_BEFORE_SPECIAL_CHARS, MASK_AFTER_SPECIAL_CHARS and GENERIC_TABLE_RANDOM_REPLACE.

Users can also implement a set of desensitization algorithms by implementing the interface provided by ShardingSphere.

**Mask table configuration:** used to tell ShardingSphere which column in the data table is used for data desensitization and which algorithm is used for desensitization.

**The mask rule takes effect after it is created**

Query attribute configuration: if both plaintext and ciphertext data are stored in the underlying database table, this attribute can be used to determine whether to query the plaintext data in the database table and return it directly, or query the ciphertext data and return it after decryption through Apache ShardingSphere.

This attribute can be configured at the table level and the entire rule level. The table-level has the highest priority.
### 12.8.3 Mask Process

For example, if there is a table in the database called `t_user` and there is a field in the table called `phone_number` that uses `MASK_FROM_X_TO_Y`, Apache ShardingSphere does not change the data store.

It’ll only mask the result according to the desensitization algorithm, to achieve the desensitization effect.

As shown in the picture below:

![Mask Process Diagram](image)

### 12.9 Shadow

#### 12.9.1 How it works

Apache ShardingSphere determines the incoming SQL via shadow by parsing the SQL and routing it to the production or shadow database based on the shadow rules set by the user in the configuration file.
In the example of an INSERT statement, when writing data, Apache ShardingSphere parses the SQL and then constructs a routing chain based on the rules in the configuration file. In the current version, the shadow feature is at the last execution unit in the routing chain, i.e. if other rules exist that require routing, such as sharding, Apache ShardingSphere will first route to a particular database according to the sharding rules, and then run the shadow routing determination process to determine that the execution SQL meets the configuration set by shadow rules. Then data is routed to the corresponding shadow database, while the production data remains unchanged.

**DML sentence**

Two algorithms are supported. Shadow determination first determines whether the execution SQL-related table intersects with the configured shadow table. If the result is positive, the shadow algorithm within the part of intersection associated with the shadow table will be determined sequentially. If any of the determination is successful, the SQL statement is routed to the shadow library. If there is no intersection or the shadow algorithm determination is unsuccessful, the SQL statement is routed to the production database.
DDL sentence

Only supports shadow algorithm with comments attached. In stress testing scenarios, DDL statements are generally not required for testing, and are used mainly when initializing or modifying shadow tables in the shadow database. The shadow determination will first determine whether the execution SQL contains comments or not. If the result is a yes, the HINT shadow algorithm configured in the shadow rules determines them in order. The SQL statement is routed to the shadow database if any of the determinations are successful. If the execution SQL does not contain comments or the HINT shadow algorithm determination is unsuccessful, the SQL statements are routed to the production database.

JAVA API: shadow database configuration
YAML configuration: shadow database

12.10 Observability

12.10.1 How it works

ShardingSphere-Agent module provides an observable framework for ShardingSphere, which is implemented based on Java Agent.

Metrics, tracing and logging functions are integrated into the agent through plugins, as shown in the following figure:
- The metrics plugin is used to collect and display statistical indicators for the entire cluster. Apache ShardingSphere supports Prometheus by default.

- The tracing plugin is used to obtain the link trace information of SQL parsing and SQL execution. Apache ShardingSphere provides support for exporting tracing data to Jaeger and Zipkin by default. It also supports users developing customized tracing components through plugin.

- The default logging plugin shows how to record additional logs in ShardingSphere. In practical applications, users need to explore according to their own needs.

### 12.11 Architecture

Apache ShardingSphere’s pluggable architecture is designed to enable developers to customize their own unique systems by adding the desired features, just like adding building blocks. A plugin-oriented architecture has very high requirements for program architecture design. It requires making each module independent, and using a pluggable kernel to combine various functions in an overlapping manner. Designing an architecture system that completely isolates the feature development not only fosters an active open source community, but also ensures the quality of the project.

Apache ShardingSphere began to focus on the pluggable architecture since version 5.X, and the functional components of the project can be flexibly extended in a pluggable manner. Currently, features such as data sharding, read/write splitting, database high availability, data encryption, shadow DB stress testing, and support for SQL and protocols such as MySQL, PostgreSQL, SQLServer, Oracle, etc.
are woven into the project through plugins. Apache ShardingSphere has provided dozens of SPIs (service provider interfaces) as extension points of the system, with the total number still increasing.
13.1 MODE

13.1.1 MODE What is the difference between standalone mode Standalone and Compatible_Standalone?

Answer:

The metadata structure was adjusted in version 5.4.0, Standalone represents the metadata structure of the new version, and Compatible_Standalone represents the metadata structure of versions before 5.4.0.

13.1.2 MODE What is the difference between cluster mode Cluster and Compatible_Cluster?

Answer:

The metadata structure was adjusted in version 5.4.0, Cluster represents the metadata structure of the new version, and Compatible_Cluster represents the metadata structure of versions before 5.4.0.

13.2 JDBC

13.2.1 JDBC Found a JtaTransactionManager in spring boot project when integrating with XAtransaction.

Answer:

1. shardingsphere-transaction-xa-core include atomikos, it will trigger auto-configuration mechanism in spring-boot, add @SpringBootApplication(exclude = JtaAutoConfiguration.class) will solve it.
Apache ShardingSphere document

13.2.2 JDBC The tableName and columnName configured in yaml or properties leading
incorrect result when loading Oracle metadata？
Answer:
Note that, in Oracle’s metadata, the tableName and columnName is default UPPERCASE, while double‐
quoted such as CREATE TABLE "TableName"("Id" number) the tableName and columnName is
the actual content double‐quoted, refer to the following SQL for the reality in metadata:
SELECT OWNER, TABLE_NAME, COLUMN_NAME, DATA_TYPE FROM ALL_TAB_COLUMNS WHERE TABLE_
NAME IN ('TableName')

ShardingSphere uses the OracleTableMetaDataLoader to load the metadata, keep the tableName
and columnName in the yaml or properties consistent with the metadata. ShardingSphere assembled
the SQL using the following code:
private String getTableMetaDataSQL(final Collection<String> tables, final
DatabaseMetaData metaData) throws SQLException {
StringBuilder stringBuilder = new StringBuilder(28);
if (versionContainsIdentityColumn(metaData)) {
stringBuilder.append(", IDENTITY_COLUMN");
}
if (versionContainsCollation(metaData)) {
stringBuilder.append(", COLLATION");
}
String collation = stringBuilder.toString();
return tables.isEmpty() ? String.format(TABLE_META_DATA_SQL, collation)
: String.format(TABLE_META_DATA_SQL_IN_TABLES, collation, tables.
stream().map(each -> String.format("'%s'", each)).collect(Collectors.joining(",
")));
}

13.2.3 JDBC SQLException: Unable to unwrap to interface com.mysql.
jdbc.Connection exception thrown when using MySQL XA transaction
Answer:
Incompatibility between multiple MySQL drivers. Because the MySQL5 version of the driver class under
the class path is loaded first, when trying to call the unwrap method in the MySQL8 driver, the type
conversion exception occurs.
The solutions: Check whether there are both MySQL5 and MySQL8 drivers in the class path, and only
keep one driver package of the corresponding version.
The exception stack is as follows:
Caused by: java.sql.SQLException: Unable to unwrap to interface com.mysql.jdbc.
Connection
at com.mysql.cj.jdbc.exceptions.SQLError.createSQLException(SQLError.java:129)

13.2. JDBC

566


13.3 Proxy

13.3.1 Proxy In Windows environment, could not find or load main class org.apache.shardingsphere.proxy.Bootstrap, how to solve it?

Answer:
Some decompression tools may truncate the file name when decompressing the ShardingSphere-Proxy binary package, resulting in some classes not being found. The solutions: Open cmd.exe and execute the following command:

```
tar zxvf apache-shardingsphere-${RELEASE.VERSION}-shardingsphere-proxy-bin.tar.gz
```

13.3.2 Proxy How to add a new logic database dynamically when use ShardingSphere-Proxy?

Answer:
When using ShardingSphere-Proxy, users can dynamically create or drop logic database through Dist-SQL, the syntax is as follows:

```
CREATE DATABASE [IF NOT EXISTS] databaseName;
DROP DATABASE [IF EXISTS] databaseName;
```

Example:

```
CREATE DATABASE sharding_db;
DROP DATABASE sharding_db;
```
13.3.3 Proxy How to use suitable database tools connecting ShardingSphere-Proxy?

Answer:

1. ShardingSphere-Proxy could be considered as a MySQL server, so we recommend using MySQL command line tool to connect to and operate it.

2. If users would like to use a third-party database tool, there may be some errors cause of the certain implementation/options.

3. The currently tested third-party database tools are as follows:
   - DataGrip: 2020.1, 2021.1 (turn on “introspect using jdbc metadata” in idea or datagrip).
   - MySQLWorkBench: 8.0.25.

13.3.4 Proxy When using a client to connect to ShardingSphere-Proxy, if ShardingSphere-Proxy does not create a database or does not register a storage unit, the client connection will fail?

Answer:

1. Third-party database tools will send some SQL query metadata when connecting to ShardingSphere-Proxy. When ShardingSphere-Proxy does not create a Database or does not register a Storage Unit, ShardingSphere-Proxy cannot execute SQL.

2. It is recommended to create database and register storage unit first, and then use third-party database tools to connect.

3. Please refer to Related introduction the details about storage unit.

13.4 Sharding

13.4.1 Sharding How to solve Cloud not resolve placeholder ...in string value ... error?

Answer:

${...} or $->{...} can be used in inline expression identifiers using the default implementation of the InlineExpressionParser SPI, but the former one clashes with place holders in Spring property files, so $->{...} is recommended to be used in Spring as inline expression identifiers.
13.4.2 Sharding Why does float number appear in the return result of inline expression?

Answer:

The division result of Java integers is also integer, but in Groovy syntax of inline expression, the division result of integers is float number. To obtain integer division result, \( A/B \) needs to be modified as \( A.\text{intdiv}(B) \).

13.4.3 Sharding If sharding database is partial, should tables without sharding database & table configured in sharding rules?

Answer:

A table that does not use sharding is called single table in ShardingSphere, and you can use LOAD statements or SINGLE rule to configure the single table that needs to be loaded.

13.4.4 Sharding When generic Long type SingleKeyTableShardingAlgorithm is used, why does the ClassCastException: Integer can not cast to Long exception appear?

Answer:

You must make sure the field in the database table is consistent with that in the sharding algorithms. For example, the field type in database is int(11) and the sharding type corresponds to generic type is Integer. If you want to configure Long type, please make sure the field type in the database is bigint.

13.4.5 [Sharding:raw-latex:PROXY] When implementing the StandardShardingAlgorithm custom algorithm, the specific type of Comparable is specified as Long, and the field type in the database table is bigint, a ClassCastException: Integer can not cast to Long exception occurs.

Answer:

When implementing the doSharding method, it is not recommended to specify the specific type of Comparable in the method declaration, but to convert the type in the implementation of the doSharding method. You can refer to the ModShardingAlgorithm#doSharding method.
13.4.6 Sharding Why is the default distributed auto-augment key strategy provided by ShardingSphere not continuous and most of them end with even numbers?

Answer:

ShardingSphere uses snowflake algorithms as the default distributed auto-augment key strategy to make sure unrepeated and decentralized auto-augment sequence is generated under the distributed situations. Therefore, auto-augment keys can be incremental but not continuous. But the last four numbers of snowflake algorithm are incremental value within one millisecond. Thus, if concurrency degree in one millisecond is not high, the last four numbers are likely to be zero, which explains why the rate of even end number is higher. In 3.1.0 version, the problem of ending with even numbers has been totally solved, please refer to: https://github.com/apache/shardingsphere/issues/1617

13.4.7 Sharding How to allow range query with using inline sharding strategy (BETWEEN AND), >, <, >=, <=)?

Answer:

1. Update to 4.1.0 above.
2. Configure (A tip here: then each range query will be broadcast to every sharding table):
   - Version 4.x: allow.range.query.with.inline.sharding to true (Default value is false).
   - Version 5.x: allow-range-query-with-inline-sharding to true in InlineShardingStrategy (Default value is false).

13.4.8 Sharding Why does my custom distributed primary key don’t work after implementing KeyGenerateAlgorithm interface and configuring type property?

Answer:

Service Provider Interface (SPI) is a kind of API for the third party to implement or expand. Except implementing interface, you also need to create a corresponding file in META-INF/services to make the JVM load these SPI implementations. More detail for SPI usage, please search by yourself. Other ShardingSphere functionality implementation will take effect in the same way.

13.4.9 Sharding In addition to internal distributed primary key, does ShardingSphere support other native auto-increment keys?

Answer:

Yes. But there is restriction to the use of native auto-increment keys, which means they cannot be used as sharding keys at the same time. Since ShardingSphere does not have the database table structure and native auto-increment key is not included in original SQL, it cannot parse that field to the sharding field. If the auto-increment key is not sharding key, it can be returned normally and is needless to be cared. But if the auto-increment key is also used as sharding key, ShardingSphere cannot parse its sharding
value, which will make SQL routed to multiple tables and influence the rightness of the application. The premise for returning native auto-increment key is that INSERT SQL is eventually routed to one table. Therefore, auto-increment key will return zero when INSERT SQL returns multiple tables.

13.5 DistSQL

13.5.1 DistSQL How to set custom JDBC connection properties or connection pool properties when adding a data source using DistSQL?

Answer:
1. If you need to customize JDBC connection properties, please take the urlSource way to define dataSource.
2. ShardingSphere presets necessary connection pool properties, such as maxPoolSize, idleTimeout, etc. If you need to add or overwrite the properties, please specify it with PROPERTIES in the dataSource.
3. Please refer to Related introduction for above rules.

13.5.2 DistSQL How to solve Storage unit [xxx] is still used by [SingleRule]. exception when dropping a data source using DistSQL?

Answer:
1. Storage units referenced by rules cannot be deleted
2. If the storage unit is only referenced by single rule, and the user confirms that the restriction can be ignored, the optional parameter ignore single tables can be added to perform forced deletion

UNREGISTER STORAGE UNIT storageUnitName [, storageUnitName] ... [ignore single tables]

13.5.3 DistSQL How to solve Failed to get driver instance for jdbcURL=xxx. exception when adding a data source using DistSQL?

Answer:
ShardingSphere Proxy do not have jdbc driver during deployment. Some example of this include mysql-connector. To use it otherwise following syntax can be used:

REGISTER STORAGE UNIT storageUnit [..., storageUnit]
13.6 Other

13.6.1 Other How to debug when SQL cannot be executed rightly in ShardingSphere?

Answer:

sql.show configuration is provided in ShardingSphere-Proxy and post-1.5.0 version of ShardingSphere-JDBC, enabling the context parsing, rewritten SQL and the routed data source printed to info log. sql.show configuration is off in default, and users can turn it on in configurations. A Tip: Property sql.show has changed to sql-show in version 5.x.

13.6.2 Other Why do some compiling errors appear? Why did not the IDEA index the generated codes?

Answer:

ShardingSphere uses lombok to enable minimal coding. For more details about using and installation, please refer to the official website of lombok. The codes under the package org.apache.shardingsphere.sql.parser.autogen are generated by ANTLR. You may execute the following command to generate codes:

```
./mvnw -DskipITs -DskipTests install -T1C
```

The generated codes such as org.apache.shardingsphere.sql.parser.autogen. PostgreSQLStatementParser may be too large to be indexed by the IDEA. You may configure the IDEA’s property idea.max.intellisense.filesize=10000.

13.6.3 Other In SQLSever and PostgreSQL, why does the aggregation column without alias throw exception?

Answer:

SQLServer and PostgreSQL will rename aggregation columns acquired without alias, such as the following SQL:

```
SELECT SUM(num), SUM(num2) FROM tablexxx;
```

Columns acquired by SQLServer are empty string and (2); columns acquired by PostgreSQL are empty sum and sum(2). It will cause error because ShardingSphere is unable to find the corresponding column. The right SQL should be written as:

```
SELECT SUM(num) AS sum_num, SUM(num2) AS sum_num2 FROM tablexxx;
```
13.6.4 Other Why does Oracle database throw “Order by value must implements Comparable” exception when using Timestamp Order By?

Answer:

```java
private List<Comparable<?>> getOrderValues() throws SQLException {
    List<Comparable<?>> result = new ArrayList<>(orderByItems.size());
    for (OrderByItem each : orderByItems) {
        Object value = queryResult.getValue(each.getIndex(), Object.class);
        Preconditions.checkState(null == value || value instanceof Comparable,
                                "Order by value must implements Comparable");
        result.add((Comparable<?>) value);
    }
    return result;
}
```

After using resultSet.getObject(int index), for TimeStamp oracle, the system will decide whether to return java.sql.TimeStamp or define oracle.sql.TIMESTAMP according to the property of oracle.jdbc.J2EE13Compliant. See oracle.jdbc.driver.TimestampAccessor#getObject(int var1) method in ojdbc codes for more detail:

```java
Object getObject(int var1) throws SQLException {
    Object var2 = null;
    if(this.rowSpaceIndicator == null) {
        DatabaseError.throwSqlException(21);
    }
    if(this.rowSpaceIndicator[this.indicatorIndex + var1] != -1) {
        if(this.externalType != 0) {
            switch(this.externalType) {
                case 93:
                    return this.getTimestamp(var1);
                default:
                    DatabaseError.throwSqlException(4);
                    return null;
            }
        }
        if(this.statement.connection.j2ee13Compliant) {
            var2 = this.getTimestamp(var1);
        } else {
            var2 = this.getTIMESTAMP(var1);
        }
    }
    return var2;
}
```
13.6.5 Other In Windows environment, when cloning ShardingSphere source code through Git, why prompt filename too long and how to solve it?

Answer:

To ensure the readability of source code, the ShardingSphere Coding Specification requires that the naming of classes, methods and variables be literal and avoid abbreviations, which may result in some source files having long names. Since the Git version of Windows is compiled using msys, it uses the old version of Windows Api, limiting the file name to no more than 260 characters. The solutions are as follows: Open cmd.exe (you need to add git to environment variables) and execute the following command to allow git supporting log paths:

```
    git config --global core.longpaths true
```

If we use windows 10, also need enable win32 log paths in registry editor or group strategy (need reboot):

- Create the registry key HKLM\SYSTEM\CurrentControlSet\Control\FileSystem LongPathsEnabled (Type: REG_DWORD) in registry editor, and be set to 1.

13.6.6 Other How to solve Type is required error?

Answer:

In Apache ShardingSphere, many functionality implementation are uploaded through SPI, such as Distributed Primary Key. These functions load SPI implementation by configuring the type, so the type must be specified in the configuration file.

13.6.7 Other How to speed up the metadata loading when service starts up?

Answer:

1. Update to 4.0.1 above, which helps speed up the process of loading table metadata.

2. Configure:

   - `max.connections.size.per.query` (Default value is 1) higher referring to connection pool you adopt (Version >= 3.0.0.M3 & Version < 5.0.0).
   - `max-connections-size-per-query` (Default value is 1) higher referring to connection pool you adopt (Version >= 5.0.0).
13.6.8 Other The ANTLR plugin generates codes in the same level directory as src, which is easy to commit by mistake. How to avoid it?

Answer:

Goto Settings -> Languages & Frameworks -> ANTLR v4 default project settings and configure the output directory of the generated code as target/gen as shown:

![Setting configuration screenshot]

13.6.9 Other Why is the database sharding result not correct when using Proxool?

Answer:

When using Proxool to configure multiple data sources, each one of them should be configured with alias. It is because Proxool would check whether existing alias is included in the connection pool or not when acquiring connections, so without alias, each connection will be acquired from the same data source. The followings are core codes from ProxoolDataSource getConnection method in Proxool:

```java
if(!ConnectionPoolManager.getInstance().isPoolExists(this.alias)) {
    this.registerPool();
}
```

For more alias usages, please refer to Proxool official website.
14.1 Latest Releases

Apache ShardingSphere is released as source code tarballs with corresponding binary tarballs for convenience. The downloads are distributed via mirror sites and should be checked for tampering using GPG or SHA-512.

14.1.1 Apache ShardingSphere - Version: 5.4.1 (Release Date: October 18th, 2023)

- Source Codes: SRC (ASC, SHA512)
- ShardingSphere-JDBC Binary Distribution: TAR (ASC, SHA512)
- ShardingSphere-Proxy Binary Distribution: TAR (ASC, SHA512)
- ShardingSphere-Agent Binary Distribution: TAR (ASC, SHA512)

14.2 All Releases

Find all releases in the Archive repository. Find all incubator releases in the Archive incubator repository.

14.3 Verify the Releases

PGP signatures KEYS

It is essential that you verify the integrity of the downloaded files using the PGP or SHA signatures. The PGP signatures can be verified using GPG or PGP. Please download the KEYS as well as the asc signature files for relevant distribution. It is recommended to get these files from the main distribution directory and not from the mirrors.
To verify the binaries/sources you can download the relevant asc files for it from main distribution directory and follow the below guide.

```
gpg --verify apache-shardingsphere-******.asc apache-shardingsphere-******
```

or

```
pgpv apache-shardingsphere-******.asc
```

or

```
pgp apache-shardingsphere-******.asc
```
